# Crystal structure and analytical profile of 1,2-di-phenyl-2-pyrrolidin-1-ylethanone hydrochloride or ' $a$-D2PV': a synthetic cathinone seized by law enforcement, along with its diluent sugar, myo-inositol 

Matthew R. Wood, ${ }^{\text {a,b }}$ Ivan Bernal ${ }^{\mathrm{a}, \mathrm{c}}$ and Roger A. Lalancette ${ }^{\mathrm{a} *}$<br>${ }^{\text {a Carl A. A confiscated package of street drugs was characterized by the usual mass spectral (MS) and FT-IR analyses. The confiscated powder material was highly crystalline and was found to consist of two very different species, accidentally of sizes convenient for X-ray diffraction. Thus, one each was selected and redundant complete sets of data were collected at 100 K using $\mathrm{Cu} K \alpha$ radiation. The selected crystals contained: (a) 1,2-diphenyl-2-(pyrrolidin-1-yl)ethanone hydrochloride hemihydrate or 1-(2-oxo-1,2-diphenylethyl)pyrrolidin-1-ium chloride hemihydrate, $\mathrm{C}_{18} \mathrm{H}_{20} \mathrm{NO}^{+} \cdot \mathrm{Cl}^{-} \cdot 0.5 \mathrm{H}_{2} \mathrm{O}$, (I), a synthetic cathinone called ' $\alpha$-D2PV', and (b) the sugar myo-inositol, $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$, (II), probably the only instance in which the drug and its diluent have been fully characterized from a single confiscated sample. Moreover, the structural details of both are rather attractive showing: (i) interesting hydrogen bonding observed in pairwise interactions by the drug molecules, mediated by the chloride counter-anions and the waters of crystallization, and (ii) $\pi-\pi$ interactions in the case of the phenyl rings of the drug which are of two different types, namely, $\pi-\pi$ stacking and edge-to- $\pi$. Finally, the inositol crystallizes with $Z^{\prime}=2$ and the resulting diastereoisomers were examined by overlay techniques.

## 1. Introduction: useful historical notes and commentaries

In 2021, as part of a law enforcement investigation, an offwhite crystalline powder was submitted for analysis. This submission contained two components: $\alpha$-pyrrolidino-2-phenylacetophenone (called $\alpha$-D2PV), which is an $N$-pyrrolidinyl substituent of natural cathinone, and myo-inositol, a common sugar. The sample was initially identified using GC-MS and the structures of both materials were confirmed by singlecrystal X-ray diffraction.
$\alpha$-D2PV, (I), belongs to a class of stimulants, 'synthetic cathinones', that are simple modifications of the chemical structure of cathinone. Cathinone is a naturally occurring chemical found in the khat plant (Catha edulis), commonly grown and used in East Africa (Kalix, 1992). Cathinone and several derivatives have been scheduled by the DEA as controlled substances, leading to the syntheses of new synthetic cathinone compounds (often referred to as 'bath salts') which were developed to produce similar psychotropic and stimulant effects as 'legal highs' (Zawilska \& Wojcieszak, 2013), and to circumvent the 'controlled substances' list. In this instance, $\alpha$-D2PV is obtained by the substitution of a

provide analytical data on as many new addictive compound(s) as become available to assist in law enforcement and toxicological investigations, which serve as an addition to a growing list of new psychotropic compounds; researchers at the University of Silesia have been adding to this list by making recent contributions (Rojkiewicz et al., 2020; Kuś et al., 2017, 2019).

Inositol has an interesting history as a natural product because it is produced by many plants, such as citrus, beans, corn, sesame, etc., and from glucose by the human body. Interestingly, the substance is not optically active because of the symmetrical hydroxylation of the six aliphatic C atoms of the cyclohexane central ring. For an interesting description of its history and early crystallographic background, we recommend the papers by Rabinovich \& Kraut (1964) [Cambridge Structural Database (CSD; Groom et al., 2016) refcode: MYINOL] and Rebecca et al. (2012) (MYINOL02). Scheme 2 shows myo-inositol, (II).

## 2. Experimental (methods and materials)

### 2.1. Sample preparation

The compound of interest was initially received as part of a law enforcement investigation of suspected controlled dangerous substances. A portion of approximately 5 mg was dissolved in 1 ml of LC-MS grade methanol supplied by Fisher Chemical (Palo Alto, CA, USA) for GC-EI-MS (gas chro-matography-electron ionization-mass spectrometry) analysis. A small portion of the sample material was ground and analyzed by ATR-FT-IR (attenuated total reflectanceFourier transform-infrared spectroscopy) without further sample preparation. A separate portion of the drug material was examined microscopically and two suitable single crystals were selected without further preparation for the X-ray diffraction experiment. Both crystals had distinctly different morphologies: the one that would prove to be the title synthetic cathinone, (I), was a colourless prism; the second, a common illicit drug diluent, the sugar inositol, (II), was a colourless parallelepiped. Additionally, a reference standard of the drug compound was purchased from Cayman Chemical (Ann Arbor, Michigan, USA) for comparison and confirmation.

### 2.2. Mass spectral analysis of (I)

The mass spectral analysis of (I) were performed using GC-EI-MS on the law-enforcement-seized sample.

Table 2
Experimental details.
Experiments were carried out at 100 K with $\mathrm{Cu} K \alpha$ radiation using a Rigaku XtaLAB Synergy Dualflex diffractometer with a HyPix detector. H atoms were treated by a mixture of independent and constrained refinement.

Computer programs: CrysAlis PRO (Rigaku OD, 2022), SHELXT2018 (Sheldrick, 2015a), SHELXL2018 (Sheldrick, 2015b), Mercury (Macrae et al., 2020) and DIAMOND (Putz \& Brandenburg, 2019).

A Thermo Scientific Trace 1310 Gas Chromatograph ISQ 7000 Mass Spectrometer [single quadrupole GC-EI-MS, utilizing a Restek Rtx-5MS (5\% diphenyl-95\% methyl crossbonded polysiloxane) $30 \mathrm{~m} \times 0.25 \mathrm{~mm}$ ID $\times 0.25 \mu \mathrm{~m}$ film column (catalogue No. 12623)] was used as part of the general drug analytical scheme of the forensic laboratory. The GC and MS parameters can be found in Table 1 and the GC spectrum of $\alpha$-D2PV, (I), is shown in Fig. 1. The mass spectral fragmentation pattern for $\alpha$-D2PV, (I), is shown in Fig. 2.

Cathinone fragmentation patterns are dominated by $\alpha$-cleavage at both the amine and the carbonyl groups. The

Figure 2
Mass spectral fragmentation of $\alpha$-D2PV, (I).
ions produced by the EI fragmentation of $\alpha-\mathrm{D} 2 \mathrm{PV}$ are consistent with previously described EI-MS fragmentation of $\alpha$-pyrrolidinophenone synthetic cathinones (Zuba, 2012; Matsuta et al., 2014; Qian et al., 2017; Davidson et al., 2020). In the case of $\alpha-\mathrm{D} 2 \mathrm{PV}$, the fragmentation produced the expected base 1-benzylidenepyrrolidinium ion at $\mathrm{m} / \mathrm{z} 160$ and the benzoylium ion at $\mathrm{m} / \mathrm{z} 105$ (Fig. 2). The proposed fragmentation mechanism (Fig. 3) is based on the extensive work of Davidson et al. (2020). Subsequent fragmentation of the 1-benzylidenepyrrolidinium ion yields a tropylium ion at 91 $\mathrm{m} / \mathrm{z}$ and the cyclopenta-1,3-diene-1-ylium ion at $65 \mathrm{~m} / \mathrm{z}$; subsequent fragmentation of the benzoylium produces a phenylium ion at $77 \mathrm{~m} / \mathrm{z}$ and the cyclobutadien-4-ylium ion at $51 \mathrm{~m} / \mathrm{z}$. Fig. 3 shows a proposed fragmentation mechanism of $\alpha$-D2PV, (I), including the possible ions involved.

### 2.3. Direct analysis of the seized drug material (I) by ATR-FT-IR

The IR spectrum (Fig. 4) was obtained with a Nicolet iS50 FT-IR spectrometer (Thermo Scientific), using attenuated total reflectance (ATR), and the spectrum was collected in the wavenumber range $4000-400 \mathrm{~cm}^{-1}$.
2.4. X-ray data collection, structure solutions, and refinements of $a$-D2PV, (I), and inositol, (II)

Crystals of (I) and (II) were secured to a micromount fiber loop using Paratone-N oil. The crystal dimensions, as well as the pertinent crystal information for both compounds, are given in Table 2. The SCXRD data for both materials were

collected at 100 K on a Rigaku XtaLAB Synergy-S Dual Source diffractometer with a PhotonJet Cu-microfocus source ( $\lambda=1.54178 \AA$ ) and a HyPix-6000HE hybrid photon counting (HPC) detector. To ensure completeness and desired redun-

Figure 5
The molecular structure of $\alpha$-D2PV, (I). The ammonium cations are linked to one another by hydrogen bonds to $\mathrm{Cl} \cdots \mathrm{H}_{2} \mathrm{O} \cdots \mathrm{Cl}$ fragments as displayed above. This view is intended primarily to show the stereochemistry of the cationic drug; however, there are additional bonding interactions linking the elements of the lattice tightly (see Figs. 5 and 6).
dancy, data collection strategies were calculated using CrysAlis PRO (Rigaku OD, 2022). Subsequent data processing was also performed in CrysAlis PRO. Using the SCALE3 ABSPACK scaling algorithm (Rigaku OD, 2022), empirical and numerical (Gaussian) absorption corrections were applied to the data (faces were determined using face-indexing in CrysAlis PRO). The structures were solved via intrinsic phasing methods using SHELXT in OLEX2 (Dolomanov et al., 2009) and refined by full-matrix least-squares techniques against $F^{2}$ (SHELXL; Sheldrick, 2015a), first in the OLEX2 (Dolomanov et al., 2009) graphical user interface, and later using SHELXTL (Sheldrick, 2015b).

All H atoms were placed either according to their electrondensity Q-peaks or were attached via the riding model in idealized positions. Data for both (I) and (II) are given in Table 2. Molecular overlay diagrams were generated using Mercury (Macrae et al., 2020) and DIAMOND (Putz \& Brandenburg, 2019).

## 3. Description of the structures

The seized crystals contain two species (easily isolated under the microscope): a colourless prism was the synthetic cathinone (I) and a colourless parallelepiped was myo-inositol (II). Fig. 5 shows the cationic amine, the chloride counter-anion, and the water of crystallization all held together by hydrogen bonds. The hydrogen bonds of the chloride anions to the protons of the ammonium N atom are important for the

Figure 7
This figure intends to show that the lattice is held together by a multitude of hydrogen bonds of the usual $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}, \mathrm{O}-\mathrm{H} \cdots \mathrm{O}$, and $\mathrm{Cl} \cdots \mathrm{H}$ types, but that, in addition, there are large numbers of meaningful hydrogenbond contacts shorter than $2.9 \AA$ that help stabilize the lattice given their size and numbers. Generic atoms labels without symmetry codes have been used.
packing, as illustrated in Figs. 6 and 7. A molecular diagram for (I) is given in the supporting information.

The overall packing is difficult to display in a single view because of its complex three-dimensional character. Fig. 6 shows additional features of the packing, which is also deceptive because it gives the impression that the cations are only linked exclusively in pairs by the $\mathrm{Cl} \cdots \mathrm{H}_{2} \mathrm{O} \cdots \mathrm{Cl}$ fragments. That such is not the case is clearly shown below.

Next, Fig. 7 shows the hydrogen bonding between the quarternary amine group of the drug, the chloride counteranion, the water of hydration, and then the chloride of the next molecule.

There are important $\pi-\pi$ interactions (see Fig. 8) between the phenyl rings of adjacent cations that cannot simultaneously be displayed in the figures described above.

The $\pi-\pi$ interactions in this crystal are very substantial; the $\mathrm{C}-\mathrm{C}$ distances between the rings range from 3.6600 (17) to 3.6985 (17) A. These belong to the short type as discussed by Janiak (2000), whose paper gives a critical account on $\pi-\pi$ stacking in metal complexes with aromatic nitrogen-containing ligands. The ring centroids here are $3.684 \AA$ apart, and the angle between the normal to the planes of the two phenyl rings is $108.9^{\circ}$.

It is interesting to note that there is another interaction between the aromatic moieties in this structure, namely, that the cations depicted in Fig. 8 also contain a face-to-edge contact depicted in Fig. 9. Note that atoms C9 and C10 (H atoms omitted for clarity) interact closely with those of C14

Figure 8
A view of the $\pi-\pi$ interactions between the arene rings of adjacent cations in (I). Generic atoms labels without symmetry codes have been used.

Figure 9
Pairs, similar to those in Fig. 7, interact as shown here. Generic atoms labels without symmetry codes have been used.
[4.3277 (18) Å] and C15 [4.690 (2) Å] (symmetry code: $x+\frac{1}{2}$, $y+\frac{1}{2}, z$ ). Thus, the entire lattice becomes very tightly bound.

### 3.1. The sugar inositol, (II) - the diluent

The sugar inositol, (II), crystallizes with two molecules in the asymmetric unit ( $Z^{\prime}=2$ ), depicted in Fig. 10. A molecular diagram for (II) is given in the supporting information.

It is clear that the pair are related by a 'near inversion' noncrystallographic center located between the $\mathrm{O} 2 / \mathrm{O} 12$ and O3/O7 pairs.

It is notable that the heavy-atom skeleton ( C and O ) matches so exactly that one can hardly discern the fact that there are two independent molecules superimposed on one another here. The most notable differences are in the cases of H 4 with H 7 and H 1 with H 10 . A list of the $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen-bond distances for (II) is given in Table 3. This superposition diagram (overlay, Fig. 11) was generated by Mercury (Groom et al., 2016) and DIAMOND (Putz \& Brandenburg, 2019).

Inositol is not chiral, which may appear as odd at first, since we are accustomed to the fact that the most common sugars

Figure 10
The two molecules of inositol, (II), in the asymmetric unit are shown with the numbering system necessary to describe the overlay diagram shown in Fig. 10.

Figure 11
Overlay diagram of the two molecules of inositol (II).
we deal with are so. However, this is a misconception inasmuch as there are many nonchiral sugars, as can be found in standard sources. Myo-inositol is an interesting sugar present in the brain, as well as other tissues, where it mediates cell transduction in response to certain hormones and neurotransmitters. It is active in processes such as growth and osmoregulation. Thus, it was of more than passing interest in finding it present in a confiscated packet of street drugs where it was obviously being used as a diluent to maximize profits of the dealers. Usually, the diluents are powdered milk or other common materials, not a more sophisticated material such as myo-isositol.

Space group and unit-cell constant determination (see Table 2) revealed that these crystals are monoclinic (space group $P 2_{1} / n$ ) and whose unit-cell constants exactly matched those of CSD refcode MYINOL02 (Rebecca et al., 2012); these two are identical having been determined at 100 K and refined to basically the same $R$ factors. But, a most important issue is that ours is the only documented sample of a street drug diluent obtained from a police seizure, whereas

Figure 12
The intricate hydrogen bonding in (II) is quite powerful. The numerical data are presented in Table 3.

MYINOL02 was obtained from an extract of Asian Dragon Fruit. Thus, the current structure must be characterized in its totality in order to be used as a reference standard for future legal proceedings.

These sugar molecules are linked by a very elaborate set of three-dimensional hydrogen bonds that are illustrated in Fig. 12.

## 4. Discussion

### 4.1. Gas chromatography

In the GC-EI-MS analysis of the drug compound $\alpha$-D2PV, (I), an additional peak was observed at retention time 11.20 min , 0.17 min after the compound of interest at 11.03 min . This peak is routinely observed in cathinone samples due to thermal degradation occurring in the injection port. In a study of 18 cathinones, including pyrrolidino examples, Kerrigan et al. (2016) described the oxidative degradation causing the loss of two H atoms, yielding the 2 Da mass shift in both the molecular ion and the base peak that was observed in the mass spectrum of the additional peak in this compound.

## 4.2. $\pi-\pi$ bonding between the drug molecules

The criterion for meaningful contacts between aromatic fragments labeled ' $\pi-\pi$ interactions' in the report by Janiak (2000) suggests that, given the experimental data available (see Figs. 7 and 8, and relevant commentary therein), the range of 3.3-3.8 $\AA$ is very reasonable indeed. Using that as an acceptable gauge, our cationic drug molecules have powerful $\pi-\pi$ interactions, which play a very obvious role in stabilizing the lattice herein described, being 3.6600 (17)-3.6985 (17) A for all six carbon pairs.

## 5. Conclusions

We were fortunate to obtain a confiscated packet of street drugs containing both the opiate and its diluent. They were completely characterized by a variety of analytical methods described above, including a full structural determination of both of its crystalline contents since, helpfully, both were present as high-quality X-ray analysis specimens.

## Acknowledgements

The X-ray diffractometer used in these studies was purchased with support from the NSF and Rutgers University. We thank
the Ocean County Sheriff's Department for continued support and initial identification of the compound. We thank Mr Robert Rauf for the MS data and analysis. The authors have declared that no competing interests exist. Author contributions: Matthew Wood and Robert Rauf did the separations and the MS measurements. Roger Lalancette collected the X-ray data. Ivan Bernal, Roger Lalancette and Matthew Wood wrote the manuscript.

## supporting information

Acta Cryst. (2024). C80, 91-97 [https://doi.org/10.1107/S2053229624000561]
Crystal structure and analytical profile of 1,2-diphenyl-2-pyrrolidin-1-ylethanone hydrochloride or ' $\alpha$-D2PV': a synthetic cathinone seized by law enforcement, along with its diluent sugar, myo-inositol

Matthew R. Wood, Ivan Bernal and Roger A. Lalancette

## Computing details

1-(2-Oxo-1,2-diphenylethyl)pyrrolidin-1-ium chloride hemihydrate (I)

## Crystal data

$2 \mathrm{C}_{18} \mathrm{H}_{20} \mathrm{NO}^{+} \cdot 2 \mathrm{Cl}^{-} \cdot \mathrm{H}_{2} \mathrm{O}$
$M_{r}=621.62$
Monoclinic, $C 2 / c$
$a=13.8926$ (1) $\AA$
$b=11.9663$ (1) $\AA$
$c=19.3872(1) \AA$
$\beta=100.384(1)^{\circ}$
$V=3170.20(4) \AA^{3}$
$Z=4$

## Data collection

Rigaku XtaLAB Synergy Dualflex diffractometer with a HyPix detector
Radiation source: micro-focus sealed X-ray tube, PhotonJet $(\mathrm{Cu})$ X-ray Source
Mirror monochromator
Detector resolution: 10.0000 pixels $\mathrm{mm}^{-1}$
$\omega$ scans
Absorption correction: multi-scan
(CrysAlis PRO; Rigaku OD, 2022)

## Refinement

Refinement on $F^{2}$
Least-squares matrix: full
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.031$
$w R\left(F^{2}\right)=0.082$
$S=1.09$
3260 reflections
203 parameters
0 restraints
Primary atom site location: structure-invariant direct methods
Secondary atom site location: difference Fourier map
$F(000)=1320$
$D_{\mathrm{x}}=1.302 \mathrm{Mg} \mathrm{m}^{-3}$
$\mathrm{Cu} K \alpha$ radiation, $\lambda=1.54184 \AA$
Cell parameters from 34597 reflections
$\theta=2.4-76.2^{\circ}$
$\mu=2.15 \mathrm{~mm}^{-1}$
$T=100 \mathrm{~K}$
Block, colourless
$0.27 \times 0.20 \times 0.11 \mathrm{~mm}$
$T_{\text {min }}=0.808, T_{\text {max }}=1.000$
58892 measured reflections
3260 independent reflections
3089 reflections with $I>2 \sigma(I)$
$R_{\text {int }}=0.043$
$\theta_{\text {max }}=76.4^{\circ}, \theta_{\text {min }}=4.6^{\circ}$
$h=-17 \rightarrow 17$
$k=-15 \rightarrow 13$
$l=-24 \rightarrow 24$

Hydrogen site location: mixed
H atoms treated by a mixture of independent and constrained refinement
$w=1 /\left[\sigma^{2}\left(F_{\mathrm{o}}^{2}\right)+(0.0404 P)^{2}+2.579 P\right]$
where $P=\left(F_{\mathrm{o}}{ }^{2}+2 F_{\mathrm{c}}{ }^{2}\right) / 3$
$(\Delta / \sigma)_{\text {max }}=0.001$
$\Delta \rho_{\text {max }}=0.26 \mathrm{e}_{\AA^{-3}}$
$\Delta \rho_{\text {min }}=-0.21 \mathrm{e} \AA^{-3}$
Extinction correction: SHELXL2018
(Sheldrick, 2015b),
$\mathrm{Fc}^{*}=\mathrm{kFc}\left[1+0.001 \mathrm{xFc}^{2} \lambda^{3} / \sin (2 \theta)\right]^{-1 / 4}$
Extinction coefficient: 0.00024 (6)

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

& \text { Block, colourless } \\
& 0.22 \times 0.10 \times 0.08 \mathrm{~mm}
\end{aligned}
$$

## Data collection

Rigaku XtaLAB Synergy Dualflex diffractometer with a HyPix detector
Radiation source: micro-focus sealed X-ray tube, PhotonJet (Cu) X-ray Source
Mirror monochromator
Detector resolution: 10.0000 pixels $\mathrm{mm}^{-1}$
$\omega$ scans
Absorption correction: gaussian
(CrysAlis PRO; Rigaku OD, 2022)

$$
\begin{aligned}
& T_{\min }=0.607, T_{\max }=1.000 \\
& 55215 \text { measured reflections } \\
& 3168 \text { independent reflections } \\
& 2697 \text { reflections with } I>2 \sigma(I) \\
& R_{\text {int }}=0.064 \\
& \theta_{\max }=76.6^{\circ}, \theta_{\min }=4.4^{\circ} \\
& h=-8 \rightarrow 8 \\
& k=-15 \rightarrow 15 \\
& l=-22 \rightarrow 23
\end{aligned}
$$

## Refinement

Refinement on $F^{2}$
Least-squares matrix: full
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.038$
$w R\left(F^{2}\right)=0.110$
$S=1.06$
3168 reflections
253 parameters
0 restraints
Primary atom site location: structure-invariant direct methods

Secondary atom site location: difference Fourier map
Hydrogen site location: mixed
H atoms treated by a mixture of independent and constrained refinement
$w=1 /\left[\sigma^{2}\left(F_{0}{ }^{2}\right)+(0.0631 P)^{2}+0.4998 P\right]$
where $P=\left(F_{\mathrm{o}}{ }^{2}+2 F_{\mathrm{c}}{ }^{2}\right) / 3$
$(\Delta / \sigma)_{\max }=0.001$
$\Delta \rho_{\max }=0.25$ e $\AA^{-3}$
$\Delta \rho_{\text {min }}=-0.26$ e $\AA^{-3}$

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Fractional atomic coordinates and isotropic or equivalent isotropic displacement parameters ( $\AA^{2}$ )
