3-Deoxy-D-galactono-1,4-lactone (3-deoxy-D-xylo-hexono-1,4-lactone)

Received 17 January 2006
Accepted 6 March 2006

On the basis of the known absolute configuration of D-galactose, the structural study of 3-deoxy-D-xylo-galactono-1,4-lactone, $C_6H_{10}O_5$ a valuable synthetic intermediate, allowed the unambiguous confirmation that the chiral centre at position 2 has the *R* configuration. This centre is formed during synthesis of the title compound from D-galactose under environmentally friendly conditions. Three symmetry-independent intermolecular hydrogen bonds link the molecules into layers parallel to the *ac* plane.

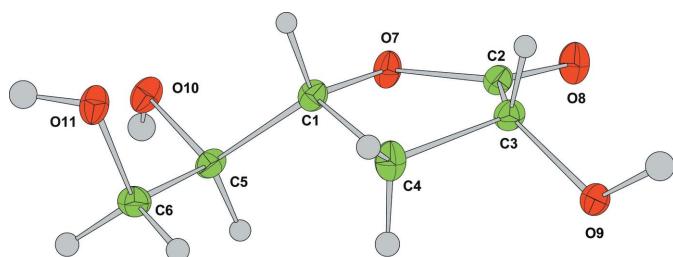

Comment

A number of useful synthetic carbohydrate scaffolds, including several branched carbohydrate lactones (Monneret & Florent, 1994) can be obtained by the treatment of hexoses with aqueous calcium hydroxide (Bols, 1996). In recent times, the deoxy lactone (1), also known as α -D-galactometasaccharinic acid, has usually been obtained by a three-step synthesis from D-galactonolactone involving organic solvents and reagents (Bock *et al.*, 1981, 1986; Choquet-Farnier *et al.*, 1997). However, a green aqueous procedure allows preparation of lactone (1) directly by treatment of galactose (2) with aqueous calcium hydroxide (Whistler & BeMiller, 1963; Kiliani & Kleeman, 1884). This is the preferred route, not only because of the environmentally friendly conditions, but also due to the low cost of galactose (2), the starting material, whose price represents just a small fraction of the cost of D-galactonolactone. It is noteworthy that completely different products arise if sugar (2) is treated with a secondary amine such as dibenzylamine prior to the reaction with calcium hydroxide; in that case the major isolated product is the branched lyxono-1,4-lactone (3) (Punzo *et al.*, 2006).

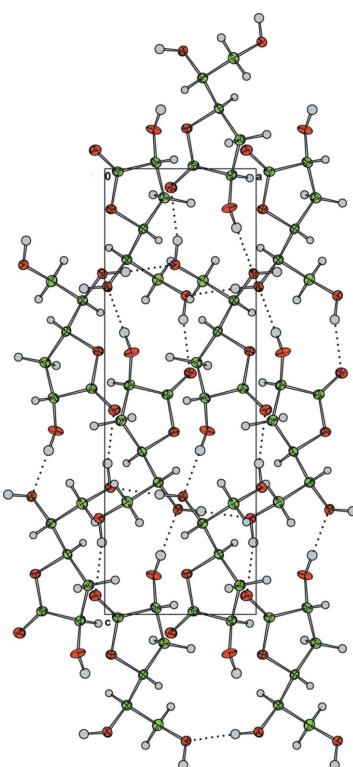

Lactone (1) can be readily obtained and has a great potential as a chiral building block for the synthesis of complex highly functionalized targets. It has already been used for the synthesis of carnitine (Bols *et al.*, 1992) and hydroxylated azepanes (Anderson *et al.*, 2000); it can also prove useful for synthesis of bulgecinines and other highly substituted prolines and pyrrolidines.

This paper reports the crystal structure of (1), prepared from galactose and calcium hydroxide, and unambiguously establishes the relative stereochemistry (Fig. 1). The use of D-

**Figure 1**

The molecular structure of (1), showing displacement ellipsoids drawn at the 50% probability level. H atoms are drawn as small circles of arbitrary radii.

**Figure 2**

Packing diagram of (1), viewed down the b axis. Hydrogen bonds are shown as dotted lines.

galactose as starting material defines the absolute configuration of the two stereogenic centres at C4 and C5; the present structural study establishes unambiguously that the chiral centre at C2 has the *R* configuration.

The packing of (1) is shown in Fig. 2. Each of the three symmetry-independent ‘active’ H atoms in the molecule of (1) is involved in hydrogen bonding (Table 2). Atoms H11 and H9 form the hydrogen bonds which link molecules into double chains along the c axis. These chains are further aggregated into layers parallel to the ac plane via hydrogen bonds involving H10.

Experimental

The title compound [m.p. 414–415 K, $[\alpha]_{21}^D -43.8$ (c 1.24 in water)] was synthesized according to Sowden *et al.* (1957) [literature m.p. 415–416 K, $[\alpha]_{25}^D -47.8$ (c 1 in water); Sowden, 1957; Sowden *et al.*,

1957)]. It was then dissolved in methanol in a small sealed glass flask and left for 24 h in an oven at 313 K and for a further night at room temperature. Thereafter, the flask was opened to let the solvent slowly evaporate and colourless prismatic crystals were formed. A suitable piece was cut from a larger crystal.

Symmetry codes: (i) $x - 1, y, z$; (ii) $-x + \frac{1}{2}, -y + 1, z + \frac{1}{2}$; (iii) $-x + \frac{1}{2}, -y + 1, z - \frac{1}{2}$.

H atoms were located in a difference map, but those attached to C atoms were repositioned geometrically. The H atoms were initially refined with soft restraints on the bond lengths and angles to regu-

larize their geometry (C—H = 0.93–98 Å and O—H = 0.82 Å) and isotropic displacement parameters [$U_{\text{iso}}(\text{H}) = 1.2\text{--}1.5U_{\text{eq}}(\text{C}, \text{O})$], after which their positions were refined with riding constraints. In the absence of significant anomalous scattering, Friedel pairs were merged.

Data collection: *COLLECT* (Nonius, 2001);; cell refinement: *DENZO/SCALEPACK* (Otwinowski & Minor, 1997); data reduction: *DENZO/SCALEPACK*; program(s) used to solve structure: *SIR92* (Altomare *et al.*, 1994); program(s) used to refine structure: *CRYSTALS* (Betteridge *et al.*, 2003); molecular graphics: *CAMERON* (Watkin *et al.*, 1996); software used to prepare material for publication: *CRYSTALS*.

Financial support from the EPSRC (to DH) is gratefully acknowledged.
