## **cis-Dichlorido(3-chloro-2-methyliminophenyl- $\kappa^2 C^1, N$ )-trans-bis(trimethylphosphine- $\kappa P$ )cobalt(III)**

**Yue Chen, Jin Zhou and Xiaoyan Li**

### S1. Comment

Reaction of chlorinated phenyl Schiff bases with  $[CoCl(PMe_3)_3]$  has been reported recently (Chen *et al.*, 2007). *N*-(2,6-Dichlorobenzylidene)methanamine reacts with  $[CoCl(PMe_3)_3]$  by a cyclometallation reaction involving C—Cl bond activation at cobalt(I) centers and with imine as pre-chelate ligands to afford the hexacoordinate title cobalt(III) complex as a red solid that is soluble in pentane or diethyl ether.

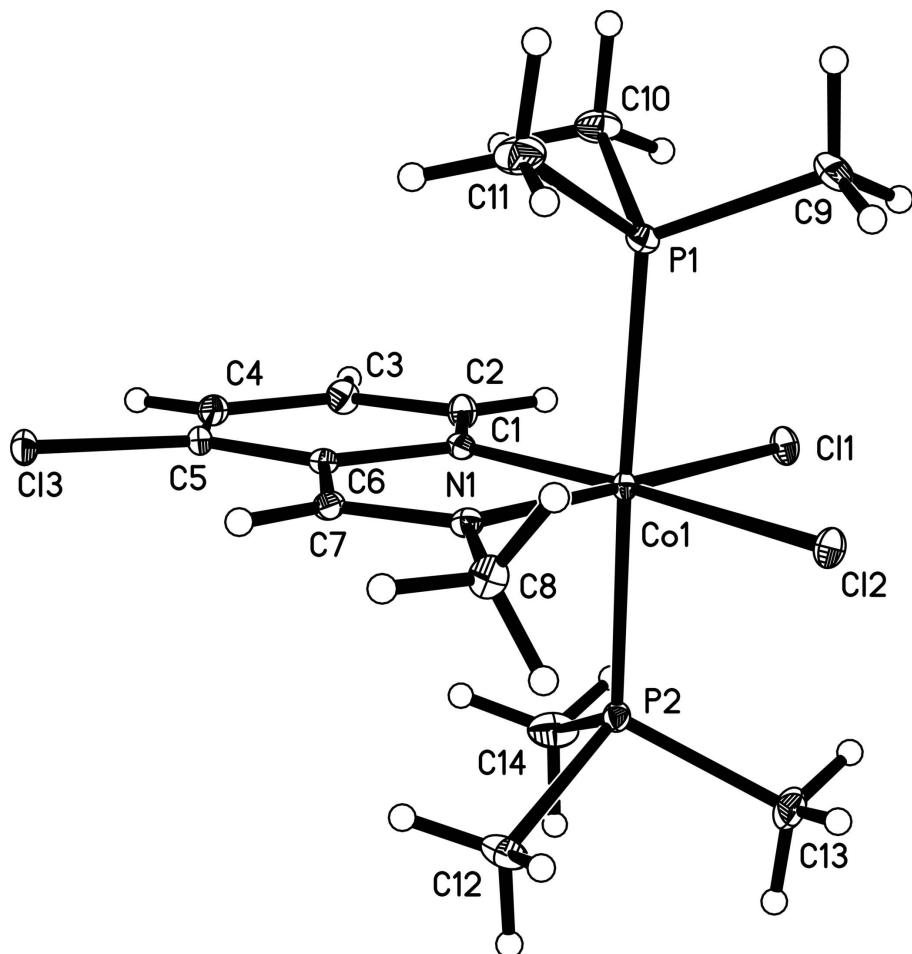

A view of the molecular structure is given in Fig. 1. The cobalt atom displays an octahedral coordination with two *cis*-chlorine atoms (Cl1 and Cl2) perpendicular to two *trans* trimethylphosphine ligands as well as *trans* to the bidentate 3-chloro-2-methyliminophenyl ligand. The P1—Co—P2 angle of 172.71 (2) $^\circ$  implies a slight distortion from an ideal octahedron. The sum of the internal angles (540 $^\circ$ ) indicates planarity of the chelate ring. The C?N bond length C7—N1 [1.288 (2) Å] is relatively long, indicating significant bond weakening upon coordination of the nitrogen donor atom. The longer Co1—Cl5 bond [2.3471 (6) Å], when compared with Co1—Cl1 [2.2742 (5) Å], reflects the stronger *trans*-influence of the carbon atom (C1) than that of the nitrogen atom (N1).

### S2. Experimental

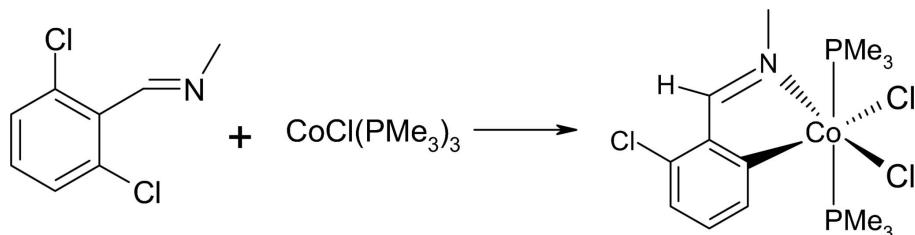

Standard vacuum techniques were used in the manipulations of volatile and air-sensitive materials. Chlorotris(trimethylphosphane)cobalt(I) (1.11 g, 3.44 mmol) was dissolved in 40 ml of tetrahydrofuran (THF). To this solution was added *N*-(2,6-dichlorobenzylidene)methanamine (0.63 g, 3.43 mmol) in 20 ml of THF at 193 K. The mixture was allowed to warm to 293 K and stirred for 18 h to form a red-brown turbid mixture. The filtrate was evaporated *in vacuo*, and the residue was extracted with pentane (60 ml) and diethyl ether (60 ml), respectively. Crystallization in diethyl ether at 246 K afforded the title complex as red crystals in 57% yield.

### S3. Refinement

The H atoms were introduced at calculated positions as riding atoms, with C—H bond lengths of 0.93 (CH) or 0.96 Å (CH<sub>3</sub>) and with  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$  or  $1.5U_{\text{eq}}(\text{C})$ , respectively.

**Figure 1**

The molecular structure of the title complex, shown with 30% probability displacement ellipsoids.

**Figure 2**

The formation of the title compound.

*Special details*

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
