Received 30 November 2007; accepted 14 December 2007

Key indicators: single-crystal X-ray study;  $T = 160$  K; mean  $\sigma(C-C) = 0.010$  Å;  $R$  factor = 0.026;  $wR$  factor = 0.059; data-to-parameter ratio = 16.2.

The half-sandwich title compound,  $[Yb_2(C_{13}H_{21})_2I_2(C_4H_{10}O)_2]$ , crystallizes as a centrosymmetric dimer. The Yb atom is coordinated in a three-legged piano-stool geometry by a cyclopentadienyl ring, two I anions and the O atom of a diethyl ether molecule. The central  $Yb_2I_2$  core is an approximate square.

## Di- $\mu$ -iodido-bis[(diethyl ether- $\kappa O$ )( $\eta^5$ -1,3-di-tert-butylcyclopentadienyl)ytterbium(II)]

Madeleine Schultz

### S1. Comment

The title compound (I) was formed in an attempt to prepare the metallocene of the substituted cyclopentadienyl ligand by stirring one equivalent of the magnesocene ( $\eta^5$ -1,3-(Me<sub>3</sub>C)<sub>2</sub>C<sub>5</sub>H<sub>3</sub>)<sub>2</sub>Mg with YbI<sub>2</sub> in diethyl ether. The reaction can also be performed using half an equivalent of magnesocene. The initial yellow-green slurry forms a deep green solution after stirring for two hours at room temperature. The green color has previously been associated with formation of an ytterbocene. However, upon filtration a thermochroic solution results that is bright-green below -30°C but becomes orange-brown upon warming to room temperature. The bright-orange crystals that form at low temperature do not redissolve in diethyl ether and are insoluble in hydrocarbon solvents. Use of THF as solvent for the reaction leads to transfer of two cyclopentadienide rings to the metal and formation of the known THF adduct [1,3-(Me<sub>3</sub>C)<sub>2</sub>C<sub>5</sub>H<sub>3</sub>]<sub>2</sub>Yb(THF) (Schumann *et al.*, 1993).

The structure of (I) is centrosymmetric about a square Yb<sub>2</sub>I<sub>2</sub> core, Fig. 1 & Table 1. There is gross thermal motion in one ethyl group of the diethyl ether ligand, affecting the thermal parameters of C(14) in particular, but this does not adversely impact the quality of the core of the structure. The distances and angles fall within normal ranges for Yb(II) in 6-coordination. (Schultz *et al.*, 2000)

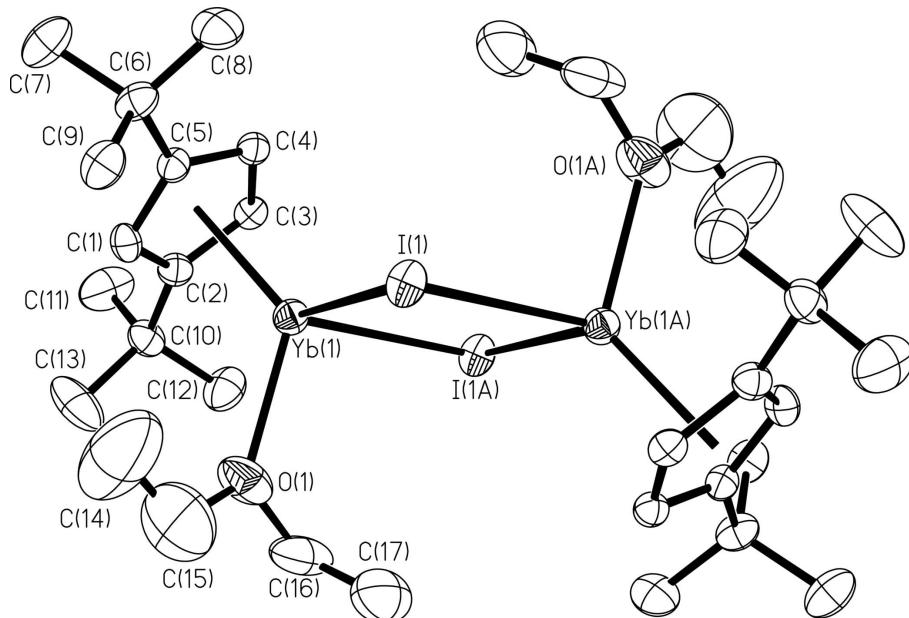

The structure is similar to those of the published dimers {(Me<sub>5</sub>C<sub>5</sub>)Yb(THF)<sub>2</sub>- $\mu$ -I}<sub>2</sub>, {(Me<sub>5</sub>C<sub>5</sub>)Yb(dme)- $\mu$ -I}<sub>2</sub>, (Constantine *et al.*, 1996) and {[Me<sub>4</sub>[SiMe<sub>2</sub>NH(CMe<sub>3</sub>)]C<sub>5</sub>]Yb(THF)<sub>2</sub>- $\mu$ -I}<sub>2</sub> (Trifonov *et al.*, 2003), in which the Yb(II) is 7-coordinate.

### S2. Experimental

The magnesocene [1,3-(Me<sub>3</sub>C)<sub>2</sub>C<sub>5</sub>H<sub>3</sub>]<sub>2</sub>Mg (0.5 g, 1.3 mmol) was weighed into a round-bottomed flask equipped with a magnetic stirrer bar. YbI<sub>2</sub> (0.56 g, 1.3 mmol) was added under a flow of N<sub>2</sub>. Et<sub>2</sub>O was added and the slurry was stirred at room temperature. After 1 h, the solution was green in color. After 3 h, the solution was filtered off the grey solid which appeared to contain unreacted magnesocene by <sup>1</sup>H NMR spectroscopy. The volume of the green solution was reduced under reduced pressure; the solid that was deposited on the sides of the flask during this procedure was orange. Cooling to -40°C resulted in the formation of clear orange crystals which were insoluble in OEt<sub>2</sub>, hot toluene or C<sub>6</sub>D<sub>6</sub>. The crystals turn brown at 130°C, and black at 230°C, but do not melt to 330°C. Analysis. Found: C 38.2, H 5.96%. C<sub>17</sub>H<sub>31</sub>IOYb requires C 37.0, H 5.67%. The insolubility of the dimer prevented recrystallization or the obtention of an NMR spectrum. Sublimation of the dimer did not lead to the formation of the ytterbocene. The ether adduct of magnesium iodide can be obtained as a first crop of colorless crystals from the mother liquor before crystallization of the orange product, and unreacted [1,3-(Me<sub>3</sub>C)<sub>2</sub>C<sub>5</sub>H<sub>3</sub>]<sub>2</sub>Mg can be crystallized from the mother liquor after all of the product has crystallized from the solution.

**S3. Refinement**

All H atoms were positioned geometrically and allowed to ride on their parent atoms with C—H distances in the range 0.93–0.97 Å, and with  $U_{\text{iso}}(\text{H}) = 1.5 U_{\text{eq}}(\text{C})$  for methyl-H atoms and  $U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{C})$  for other atoms. The maximum and minimum residual electron density peaks of 0.92 and -1.11 e Å<sup>-3</sup> were located 0.94 and 0.94 Å, respectively from the H15A and Yb atoms.

**Figure 1**

A view of the dimer (I) showing the atom labelling scheme. Hydrogen atoms have been omitted for clarity and displacement ellipsoids are drawn at the 50% probability level. Symmetry operation i:  $-x + 2, -y + 1, -z + 1$ .

*Special details*

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
