Bis(2-amino-4-methylpyridinium) terephthalate tetrahydrate

Madhukar Hemamalini and Hoong-Kun Fun*‡

X-ray Crystallography Unit, School of Physics, Universiti Sains Malaysia, 11800 USM, Penang, Malaysia

Correspondence e-mail: hkfun@usm.my

Received 28 June 2010; accepted 30 June 2010

 Key indicators: single-crystal X-ray study; $T = 100$ K; mean $\sigma(\text{C}-\text{C}) = 0.003$ Å; R factor = 0.036; wR factor = 0.101; data-to-parameter ratio = 9.4.

In the crystal structure of the title salt, $2\text{C}_6\text{H}_9\text{N}_2^+\cdot\text{C}_8\text{H}_4\text{O}_4^{2-}\cdot 4\text{H}_2\text{O}$, the terephthalate carboxylate groups interacts with the 2-amino-4-methylpyridinium cations *via* a pair of $\text{N}-\text{H}\cdots\text{O}$ hydrogen bonds, forming an $R_2^2(8)$ ring motif. The water molecules form an $R_6^6(12)$ ring motif through $\text{O}-\text{H}\cdots\text{O}$ hydrogen bonds and these motifs are fused, forming a supramolecular chain along the c axis. The $R_2^2(8)$ and $R_6^6(12)$ ring motifs are connected *via* $\text{O}-\text{H}\cdots\text{O}$ hydrogen bonds. In addition, $\pi-\pi$ stacking interactions are observed between the pyridinium rings [centroid-centroid distance = $3.522(12)$ Å].

Bis(2-amino-4-methylpyridinium) terephthalate tetrahydrate**Madhukar Hemamalini and Hoong-Kun Fun****S1. Comment**

Supramolecular architectures assembled *via* various delicate noncovalent interactions such as hydrogen bonds, π - π stacking and electrostatic interactions, etc., have attracted intense interest in recent years because of their fascinating structural diversity and potential applications for functional materials (Desiraju, 2007; Corna *et al.*, 2004). Especially, the application of intermolecular hydrogen bonds is a well known and efficient tool in the field of organic crystal design owing to its strength and directional properties (Aakeröy & Seddon, 1993). Pyridine and its derivatives play an important role in heterocyclic chemistry (Pozharski *et al.*, 1997; Katritzky *et al.*, 1996). They are often involved in hydrogen-bond interactions (Jeffrey & Saenger, 1991; Jeffrey, 1997; Scheiner, 1997). Terephthalic acid (H₂TPA), a rod-like aromatic diacid, has often been used in the synthesis of metal-organic frameworks as a linker molecule (Serre *et al.*, 2007; Mukherjee *et al.*, 2004; Sun *et al.*, 2000). Recently, with the increase in interest in controlling the crystalline structures of organic-based solid-state materials, H₂TPA is being increasingly employed in constructing supramolecular structures (Lynch & Jones, 2004; Spencer *et al.*, 2004; Devi & Muthiah, 2007). Since our aim is to study some interesting hydrogen-bonding interactions, the crystal structure of the title compound is presented here.

The asymmetric unit of the title salt contains two 2-amino-4-methylpyridinium cations (A and B), one terephthalate anion and four water molecules (Fig. 1). Each 2-amino-4-methylpyridinium cation is planar, with a maximum deviation of 0.008 (2) Å for atom C2A (molecule A) and 0.005 (2) Å for atom C3B (molecule B). The protonation of atoms N1A and N1B lead to a slight increase in C1A—N1A—C5A [122.10 (16)°] and C1B—N1B—C5B [122.09 (16)°] angles. The bond lengths (Allen *et al.*, 1987) and angles are normal.

In the crystal structure, the terephthalate carboxylate groups interacts with 2-amino-4-methylpyridinium cations *via* a pair of N—H \cdots O hydrogen bonds, forming an $R_2^2(8)$ ring motif (Bernstein *et al.*, 1995). An $R_6^6(12)$ ring motif is formed by water molecules through O—H \cdots O (Table 1) hydrogen bonds and these motifs fuse to form a one-dimensional supramolecular chain along the *c*-axis (Fig. 2). Further, the $R_2^2(8)$ and $R_6^6(12)$ motifs are connected *via* O—H \cdots O hydrogen bonds (Fig. 3). The crystal structure is further stabilized by π - π interactions between N1A/C1A—C5A and N1B/C1B—C5B pyridinium rings at (x, y, z) [centroid-to-centroid distance = 3.522 (1) Å].

S2. Experimental

A hot methanol solution (20 ml) of 2-amino-4-methylpyridine (54 mg, Aldrich) and terephthalic acid (83 mg, Merck) were mixed and warmed over a heating magnetic stirrer hotplate for a few minutes. The resulting solution was allowed to cool slowly at room temperature and crystals of the title compound appeared after a few days.

S3. Refinement

O- and N-bound H atoms were located from a difference Fourier map and were refined freely [N—H = 0.83 (3)–1.01 (5) Å and O—H = 0.75 (3)–0.92 (3) Å]. The remaining hydrogen atoms were positioned geometrically [C—H = 0.93 or 0.96 Å]

and were refined using a riding model, with $U_{\text{iso}}(\text{H}) = 1.2$ or $1.5 U_{\text{eq}}(\text{C})$. A rotating group model was used for the methyl groups. In the absence of significant anomalous dispersion, 2680 Friedel pairs were merged before the final refinement.

 $\Delta\rho_{\min} = -0.20 \text{ e } \text{\AA}^{-3}$

Special details

Experimental. The crystal was placed in the cold stream of an Oxford Cryosystems Cobra open-flow nitrogen cryostat (Cosier & Glazer, 1986) operating at 100.0 (1) K.

Geometry. All s.u.'s (except the s.u. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell s.u.'s are taken into account individually in the estimation of s.u.'s in distances, angles and torsion angles; correlations between s.u.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell s.u.'s is used for estimating s.u.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R-factor wR and goodness of fit S are based on F^2 , conventional R-factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\sigma(F^2)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on F^2 are statistically about twice as large as those based on F , and R-factors based on ALL data will be even larger.
