Received 16 August 2010; accepted 25 August 2010

Key indicators: single-crystal X-ray study; $T = 100\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.002\text{ \AA}$; R factor = 0.033; wR factor = 0.096; data-to-parameter ratio = 12.8.

The title compound, known as odorine or roxburghilinone [systematic name: (*S*)-*N*-[(*R*)-1-cinnamoylpyrrolidin-2-yl]-2-methylbutanamide], $\text{C}_{18}\text{H}_{24}\text{N}_2\text{O}_2$, is a nitrogenous compound isolated from the leaves of *Aglaia odorata*. The absolute configuration was determined by refinement of the Flack parameter with data collected using $\text{Cu } K\alpha$ radiation showing positions 2 and 2' to be *S* and *R*, respectively. The pyrrolidine ring adopts an envelope conformation. In the crystal, molecules are linked into chains along [010] by intermolecular N–H···O hydrogen bonds.

Absolute configuration of odorine

Hoong-Kun Fun, Suchada Chantrapromma, Orapun Yodsoue and Chatchanok Karalai

S1. Comment

Several species of the genus *Aglaia* of the family Meliaceae are of ethnomedicinal values and have insecticidal (Brader *et al.*, 1998), antifungal (Engelmeier *et al.*, 2000) and cytotoxic (Saifah *et al.*, 1993; Cui *et al.*, 1997) activities. These interesting activities have prompted us to screen for further bioactive compounds from *Aglaia odorata*. *Aglaia odorata* known locally in Thai as "Pra-yong" or "Hom-glai" is a small tree occurring primarily in South-East Asia. The leaves and roots of this plant have been used in local folk medicine as a heart stimulant, febrifuge and to retrieve toxin by causing vomiting. The isolated compounds from this plant also show interesting biological activities such as anticancer (Inada *et al.*, 2001), insecticidal (Nugroho *et al.*, 1999) and anti-leukemic (Hayashi *et al.*, 1982) activities. In the course of our research of chemical constituents and bioactive compounds from the leaves of *A. odorata* which were collected from Songkhla province in the southern part of Thailand, the title aminopyrrolidine odorine (I), also known as odorine (Shiengthong *et al.*, 1979) or roxburghiline or *N*-cinnamoyl-2-(2-methylbutanoylamino)pyrrolidine (Purushothaman *et al.*, 1979) was isolated. The previous report showed that (I) possesses cancer-chemopreventive activity (Inada *et al.*, 2001). The absolute configuration of (I) was determined by making use of the anomalous scattering of Cu K α *X*-radiation with the Flack parameter being refined to 0.03 (18). We report herein the crystal structure of (I).

Fig. 1 shows that the molecule of (I) possesses a 2-aminopyrrolidine ring linked by two amide functions to 2-methylbutyric acid and cinnamic acid. The pyrrolidine ring adopts an envelope conformation with the puckered C12 atom having a deviation of 0.223 (1) Å and with the puckering parameters Q = 0.3522 (15) Å and θ = 281.3 (2) $^\circ$ (Cremer & Pople, 1975). Atoms of the cinnamoyl (C1–C9/O1) moiety essentially lie on the same plane (*r.m.s.* 0.0216 (1) Å) with a max. deviation of 0.0583 (1) Å for atom O1. Atoms C13, C14, C15, N2 and O2 lie on the same plane (*r.m.s.* 0.0216 (1) Å). The mean plane through C13/C14/C15/N2/O2 makes the dihedral angle of 88.80 (7) $^\circ$ with the mean plane through the cinnamoyl moiety. The 2-methylbutanamide chain at C13 is pseudo-axial with the C14–N2–C13–C12 torsion angle = 125.55 (13) $^\circ$. The orientation of the butyl group is described by the torsion angle C14–C15–C17–C18 = 68.78 (18) $^\circ$. The bond distances in (I) are within normal ranges (Allen *et al.*, 1987) and comparable with the related structures which are odorinol (Hayashi *et al.*, 1982) and forbaglin A (Dumontet *et al.*, 1996). The absolute configuration at atoms C15 and C13 or positions 2 and 2' of the odorine are *S,R* configurations which agree with the previous stereochemistry of odorine (Babidge *et al.*, 1980).

In the crystal packing of (I) (Fig. 2), the molecules are linked into chains along [010] through N2—H1N2 \cdots O1ⁱ hydrogen bonds (Fig. 2 and Table 1).

S2. Experimental

Ground-dried leaves of *A. odorata* (53.70 g) were extracted with CH₂Cl₂ and CH₃OH (each of 2 \times 2 L) for a duration of 3 days at room temperature. The solvents were evaporated under reduced pressure to afford CH₂Cl₂ (23.50 g) and CH₃OH (5.23 g) crude extracts, respectively. The CH₂Cl₂ crude extract (23.50 g) was further purified by quick column

chromatography (QCC) over silica gel using hexane as eluent and increasing polarity with EtOAc and CH₃OH to afford 10 fractions (F1-F10). Fraction F10 (231.6 mg) was further separated by column chromatography with acetone-hexane (3:7), yielding the title compound as white solid (15.6 mg). Colorless needle-shaped single crystals of the title compound suitable for *x*-ray structure determination were recrystallized from CH₂Cl₂ by the slow evaporation of the solvent at room temperature after several days, Mp. 476-478 K.

S3. Refinement

The amide H atom was located in a difference map and refined isotropically. The remaining H atoms were placed in calculated positions with (C—H) = 0.98 for CH, 0.97 for CH₂ and 0.96 Å for CH₃ atoms. The *U*_{iso} values were constrained to be 1.5*U*_{eq} of the carrier atom for methyl H atoms and 1.2*U*_{eq} for the remaining H atoms. A rotating group model was used for the methyl groups. The highest residual electron density peak is located at 0.73 Å from C6 and the deepest hole is located at 0.71 Å from C9. 1036 Friedel pairs were used to determine the absolute configuration.

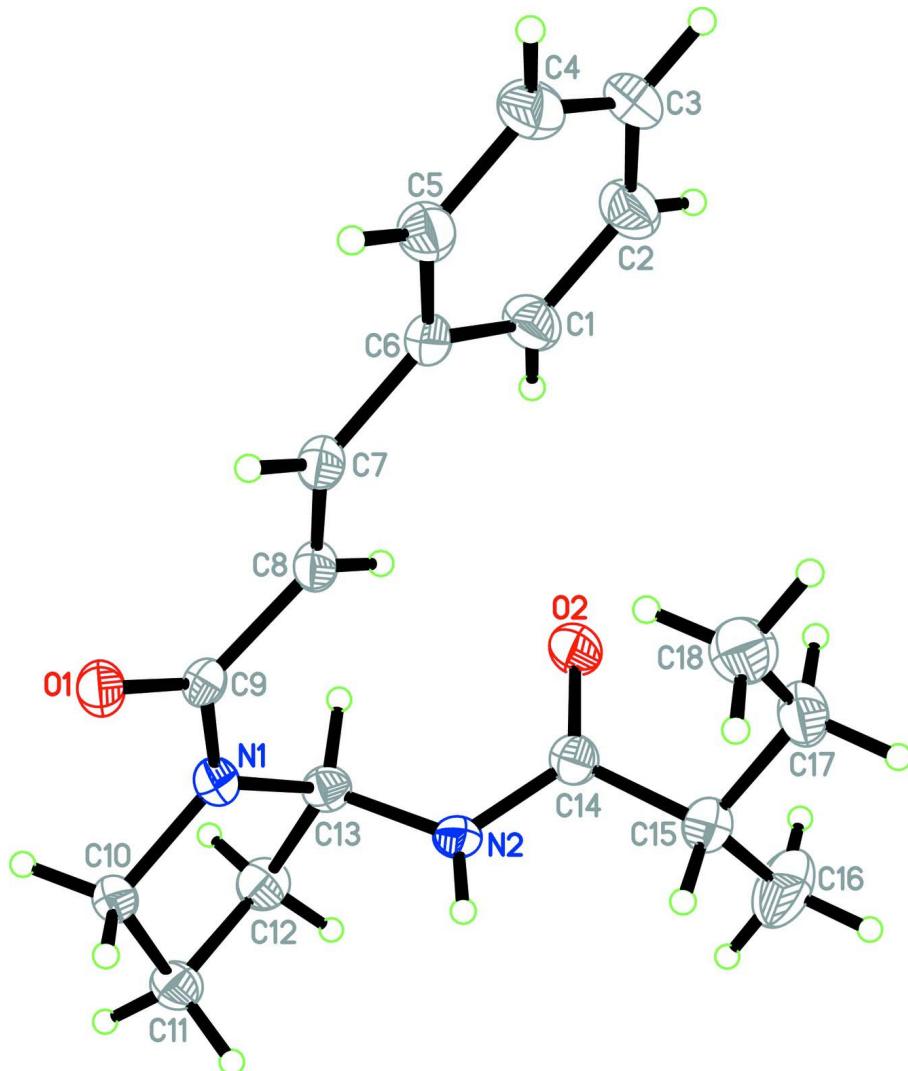

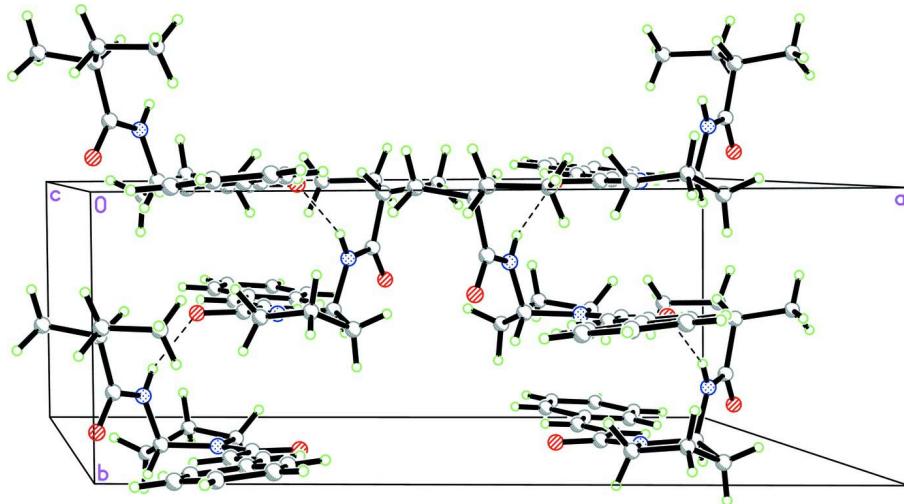

Figure 1

The molecular structure of (I), showing 50% probability displacement ellipsoids and the atom-numbering scheme.

**Figure 2**

The crystal packing of (I) viewed approximately along the c axis, showing one dimensional chains along [0 1 0]. N—H···O hydrogen bonds are shown as dashed lines.

Special details

Experimental. The crystal was placed in the cold stream of an Oxford Cryosystems Cobra open-flow nitrogen cryostat (Cosier & Glazer, 1986) operating at 100.0 (1) K.

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R-factor wR and goodness of fit S are based on F^2 , conventional R-factors R are based on F, with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\text{sigma}(F^2)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on F^2 are statistically about twice as large as those based on F, and R-factors based on ALL data will be even larger.
