Received 19 November 2010; accepted 23 November 2010

Key indicators: single-crystal X-ray study; $T = 295\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.007\text{ \AA}$; R factor = 0.058; wR factor = 0.234; data-to-parameter ratio = 11.7.

In the crystal, the inversely oriented molecules of the title compound, $\text{C}_{15}\text{H}_9\text{BF}_2\text{O}_3$, form stacks along the a axis via $\pi-\pi$ interactions between parallel phenylchromenium fragments. Linked by a network of $\text{C}-\text{H}\cdots\text{F}$ interactions, the stacks form layers in the ac plane that are dispersively stabilized in the crystal structure. Two F atoms bonded to the B atom are located in the plane perpendicular to the planar skeleton of the molecule made rigid by two intramolecular $\text{C}-\text{H}\cdots\text{O}$ interactions.

2,2-Difluoro-4-phenyl-1,3,2-dioxaborolo[4,5-c]chromen-5-ium-2-ide

Michał Wera, Alexander D. Roshal and Jerzy Błażejowski

S1. Comment

3-Hydroxy-2-phenyl-4*H*-chromene-4-one (flavonol) and its derivatives have been investigated for a long time owing to their unique spectral properties emerging from the excited state intramolecular proton transfer occurring in them (Sytnik *et al.*, 1994). These compounds turned out to be convenient analytical probes because of their considerable ability to complex various chemical entities (molecules, ions) (Roshal *et al.*, 1998; Roshal *et al.*, 2003; Petković *et al.*, 2010). The latter property was the reason for turning our attention to the possibility of applying of flavonol as an analytical spectral probe for boron compounds (Roshal *et al.*, 2002). As part of these investigations we wanted to see how flavonol behaved in the presence of BF_3 . Thus we mixed both reagents in dichloromethane, expecting to obtain a molecular complex of flavonol and BF_3 . The structure of the crystalline product that was actually separated is presented here. It appears that not complexation but condensation of the two reagents, accompanied by the release of HF, takes place (Kukharenko & Avramenko, 2001) and a molecule of a formally zwitterionic canonical structure was produced. Crystal structures of various flavonol complexes have so far been reported (Farina & Yamin, 1995; Belogh-Hergovich *et al.*, 1999; Okabe *et al.*, 2003; Kaizer *et al.*, 2007), but none of them have contained boron.

The canonical structure of the title compound suggests that the phenylchromenium core of the molecule is aromatic. This is confirmed by analysis of the bond lengths and angles, as well as comparison of the structure determinated here with the structures of selected compounds containing flavonol units (Farina *et al.*, 1995; Belogh-Hergovich *et al.*, 1999; Okabe *et al.*, 2003; Kaizer *et al.*, 2007). Furthermore, the average deviation from planarity of the phenylchromenium core is 0.0215 (2) and that of the molecule's skeleton is 0.0373 (2). This implies that both the above-mentioned molecular fragments are planar and that two F atoms at the B atom are located in a plane perpendicular to the molecular one (the dihedral angle between the plane of the molecule's skeleton and the plane of B1–F1–F2 is 89.5 (1) $^\circ$). Furthermore, two intramolecular C–H···O interactions (Table 1, Fig. 1) stiffen the phenylchromenium core, undoubtedly contributing to its planarity.

In the crystal structure, inversely oriented molecules form stacks along the *a* axis *via* π – π interactions between parallel phenylchromenium fragments (Table 2, Figs. 2 and 3). These stacks are linked by a network of C–H···F interactions arranged in layers in the *ac* plane (Table 1, Figs. 2 and 3). The above-mentioned layers are dispersively stabilized in the crystal lattice. The C–H···O (Novoa *et al.*, 2006) and C–H···F (Thalladi *et al.* (1998); Choudhury & Guru Row (2004)) interactions are of the hydrogen bond type. Like the π – π contacts, they are of an attractive nature (Hunter *et al.*, 2001).

S2. Experimental

The title compound was obtained during the reaction of 3-hydroxy-2-phenyl-4*H*-chromene-4-one (flavonol) with BF_3 (Roshal *et al.*, 2002). Thus, boron trifluoride dissolved in anhydrous diethyl ether was added dropwise, with continuous stirring, to an equimolar amount of a saturated solution of flavonol in anhydrous dichloromethane. After evaporation of the solvents, the residue was recrystallized twice from *N,N*-dimethylformamide yielding yellow fluorescing crystals

suitable for X-Ray investigations (m.p. 485 - 487 K).

S3. Refinement

H atoms were positioned geometrically, with C—H = 0.93 Å, and constrained to ride on their parent atoms with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$.

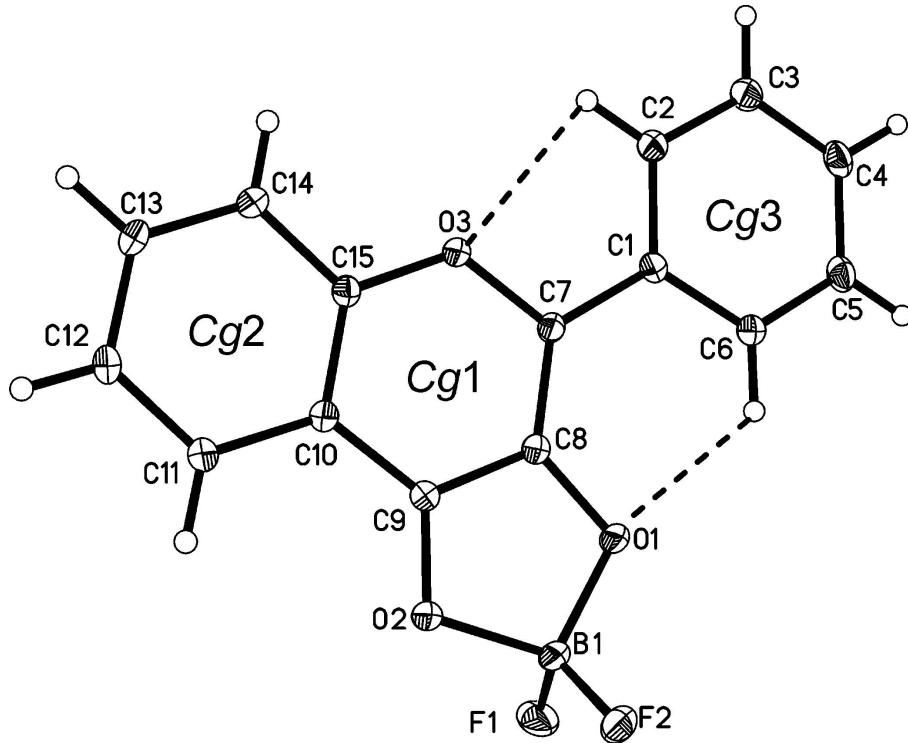

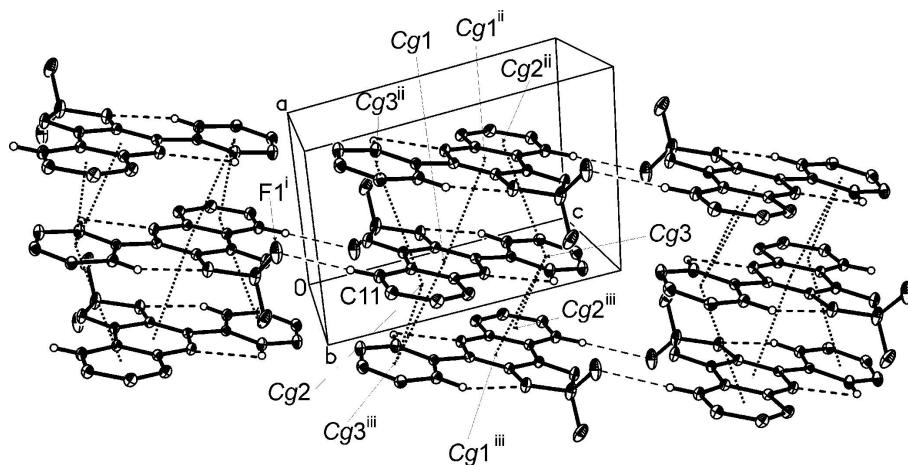

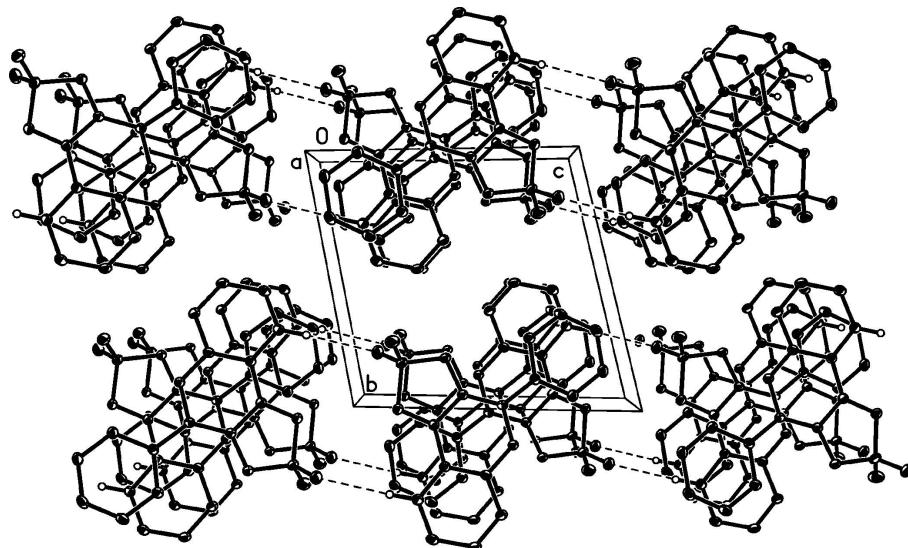

Figure 1

The molecular structure of the title compound showing the atom-labeling scheme. Displacement ellipsoids are drawn at the 25% probability level, and H atoms are shown as small spheres of arbitrary radius. $Cg1$, $Cg2$ and $Cg3$ denote the ring centroids. The C—H···O hydrogen bonds are represented by dashed lines.

**Figure 2**

The arrangement of the molecules in the crystal structure. The C–H···O and C–H···F interactions are represented by dashed lines, the π – π contacts by dotted lines. H atoms not involved in interactions have been omitted. [Symmetry codes: (i) $-x + 1, -y, -z$; (ii) $-x + 1, -y, -z + 1$; (iii) $-x, -y, -z + 1$.]

**Figure 3**

Molecular stacks in the crystal structure, viewed along the a axis. The C–H···F interactions are represented by dashed lines. H atoms not involved in interactions have been omitted.

Refinement

Refinement on F^2
Least-squares matrix: full
 $R[F^2 > 2\sigma(F^2)] = 0.058$
 $wR(F^2) = 0.234$
 $S = 1.10$
2218 reflections
190 parameters
0 restraints
Primary atom site location: structure-invariant direct methods

Secondary atom site location: difference Fourier map
Hydrogen site location: inferred from neighbouring sites
H-atom parameters constrained
 $w = 1/[\sigma^2(F_o^2) + (0.0787P)^2 + 0.4107P]$
where $P = (F_o^2 + 2F_c^2)/3$
 $(\Delta/\sigma)_{\max} < 0.001$
 $\Delta\rho_{\max} = 0.22 \text{ e \AA}^{-3}$
 $\Delta\rho_{\min} = -0.24 \text{ e \AA}^{-3}$

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
