Received 5 March 2012; accepted 23 March 2012

Key indicators: single-crystal X-ray study; $T = 293$ K; mean $\sigma(\text{C}-\text{C}) = 0.004$ Å; R factor = 0.057; wR factor = 0.243; data-to-parameter ratio = 14.2.

The structure of the title compound, $\{(\text{N}_2\text{H}_5)[\text{Li}_3(\text{C}_6\text{H}_2\text{N}_2\text{O}_4)_2(\text{H}_2\text{O})_2]\cdot\text{H}_2\text{O}\}_n$, is composed of molecular dimers, each built up of two symmetry-related Li^{I} ions with distorted trigonal-bipyramidal coordinations bridged by two deprotonated ligand molecules *via* their *N,O*-bonding sites. Doubly solvated Li^{I} ions with a distorted tetrahedral geometry link adjacent dimers, forming a polymer generated by bridging bidentate carboxylato O atoms to Li^{I} ions in adjacent dimers, forming anionic layers parallel to the *ac* plane with mono-protonated hydrazinium cations and crystal water molecules positioned between them. The layers are held together by an extended system of hydrogen bonds in which the hydrazinium cations and coordinated and crystal water molecules act as donors and carboxylate O atoms act as acceptors.

Related literature

For the crystal structures of Li^{I} complexes with pyridazine-3,6-dicarboxylate ligands, see: Starosta & Leciejewicz (2010, 2011, 2012). The structure of a hydrazine adduct of pyridazine-3,6-dicarboxylic acid was also reported by Starosta & Leciejewicz (2008).

Poly[hydrazin-1-ium [diaquabis(μ_4 -pyridazine-3,6-dicarboxylato)trilithate] monohydrate]

Wojciech Starosta and Janusz Leciejewicz

S1. Comment

It has been reported (Starosta & Leciejewicz, 2010), that the structure of a Li^{I} complex with pyridazine-3,6-dicarboxylate and water ligands is built of centrosymmetric monomers bridged by strong, centrosymmetric hydrogen bonds.

Deprotonization by an addition of a small amount of hydrazine resulted in a compound with a polymeric structure composed of centrosymmetric tetramers in which two Li^{I} ions, bridged by two fully deprotonated pyridazine-3,6-dicarboxylate ligands are linked to two triply solvated Li^{I} ions. The latter bridge the tetramer *via* two aqua O atoms to adjacent tetramers (Starosta & Leciejewicz, 2011). An addition of few more drops of hydrazine gave rise to a compound with a structure built of centrosymmetric anions in which two Li^{I} ions, are bridged by two fully deprotonated pyridazine-3,6-dicarboxylate ligands with the charge compensated by two mono protonated hydrazine cations and neutral centrosymmetric tetrameric molecules as in previous compound. While studying the reaction products of LiNO_3 with the title ligand we have obtained a new compound. Its structure is reported below. The structure of the title compound is polymeric. Its unit cell contains two symmetry independent dinuclear moieties (dimers) related by a centre of symmetry each built of two Li ions and two fully deprotonated pyridazine-3,6-dicarboxylate ligands (Fig. 1). The dimers are bridged by a doubly solvated symmetry independent Li^{III} ion. In each dimer, ligand carboxylate groups act as bidentate. Apart from participation in the *N,O*-bonding groups chelating the intra-dimer Li ions, they use the second O atoms to bridge the dimers to doubly solvated Li^{III} ions forming an anionic ribbon propagating in the unit cell *c* direction (Symmetry code: ⁱ $-x + 1, -y + 2, -z + 1$; ⁱⁱ $-x + 2, -y + 2, -z + 1$; ^{iv} $-x + 2, -y + 2, -z$; ^v $x + 1, y, z$)(Fig. 1). A second bridging pathway with a direction normal to the ribbons links them into a polymeric two-dimensional framework (Fig. 2). The two dimers and two doubly solvated Li^{III} ions carry a charge of (2-) which is compensated by two inversion symmetry related mono-protonated hydrazinium cations positioned between adjacent dimers. In the asymmetric unit there is a crystal water molecule. The coordination polyhedron around the Li1 ion, a distorted trigonal-bipyramid, is composed of O13, O12ⁱ, N12ⁱⁱ atoms which make an equatorial plane, the Li1 ion is 0.0863 (2) Å out of it, N11 and O11ⁱⁱ atoms are at apical positions. The strongly distorted trigonal-bipyramidal coordination of the Li2 ion consists of N21, O22^v and O24^{iv} atoms which constitute its equatorial plane with the Li2 ion 0.0893 (2) Å out of it; O21 and N22^{iv} atoms are at the apices. The penta-coordination mode of Li1 and Li2 ions can be also visualized as a transition from distorted trigonal-bipyramid to a deformed square-pyramid, the latter with O12ⁱ and O24^{iv} atoms at apical positions in case of Li1 and Li2 ions, respectively. Li—O and Li—N bond distances (Table 1) fall in the same range as those observed in the Li^{I} complexes with title and water ligands (Starosta & Leciejewicz, 2010, 2011, 2012). The ligand 1 and 2 pyridazine rings are planar with r.m.s. of 0.0123 (2) Å and 0.0077 (1) Å, respectively. The carboxylate groups C17/O11/12 and C18/O13/O14 make dihedral angles with the ligand ring 1 of 17.8 (2)° and 13.3 (2)°, respectively; the respective angles between C27//O21/O22 and C28/O23/24 groups and the ligand ring 2 are 15.9 (2)° and 8.4 (2)°. Li^{III} ion shows a distorted

tetrahedral coordination geometry with a pair of bridging carboxylato O13 and O23 atoms and a pair of coordinated water O1, O2 atoms in *trans* arrangement. Li3 ion is neither coplanar with the dimer 1 nor the dimer 2 as indicated by the O14—Li3—O23 angle of 110.6 (3)°; its position in respect to adjacent dimers makes a half-open cavity which is occupied by the hydrazinium cation. The layers are held together by an extended system of hydrogen bonds in which hydrazinium cation, coordinated, and crystal water molecules act as donors to carboxylato O atoms (Table 2).

S2. Experimental

A reaction of 1 mmol of pyridazine-3,6-dicarboxylic acid with 2 mmol s of lithium nitrate both dissolved in 50 ml of hot water and then boiled under reflux with stirring for 6 h yielded a compound which was identified by its lattice parameters as that one reported earlier (Starosta & Leciejewicz, 2010). After an addition of few drops of hydrazine, its warm aqueous solution was stirred for two h without heating. Left to crystallize at room temperature, single-crystal plates of the title compound were found after a couple of days. They were washed with cold ethanol and dried in air.

S3. Refinement

Coordinated water, hydrazine hydrogen atoms and crystal water molecule were located in a difference map and refined isotropically, while H atoms attached to pyridazine-ring C atoms were located at calculated positions and treated as riding on the parent atoms with C—H=0.93 Å and $U_{\text{iso}}(\text{H})=1.2U_{\text{eq}}(\text{C})$.

Figure 1

A molecule of the title compound with atom labelling scheme and 50% probability displacement ellipsoids. For clarity, hydrogen atoms are not labelled. Symmetry code: ⁱ $-x + 1, -y + 2, -z + 1$; ⁱⁱ $-x + 2, -y + 2, -z + 1$; ^{iv} $-x + 2, -y + 2, -z$; ^v $x + 1, y, z$.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
