Supporting information: this article has supporting information at journals.iucr.org/e

The title compound, $[\text{Ag}(\text{qPyr})_2]\text{CF}_3\text{SO}_3$ where $\text{qPyr} = 1\text{-}(\text{quinoline-2-ylmethylene})\text{aminopyrene}$, $\text{C}_{26}\text{H}_{16}\text{N}_2$, was synthesized from a reaction of silver trifluoromethanesulfonate and qPyr in dichloromethane–methanol mixed media. In this design, the qPyr ligand was chosen for its characteristic excitation and emission profiles, which could enable the tracking of the silver complex within biological targets. The Ag^{I} atom resides in a distorted tetrahedral N_4 coordination sphere. Analysis of the packing pattern revealed significant intra- and intermolecular π – π stacking interactions between the $[\text{Ag}(\text{qPyr})_2]^+$ cations. In addition, a weak $\text{C}–\text{H} \cdots \text{O}$ hydrogen bond consolidates the packing between cations and anions.

1. Chemical context

Silver metal and its salts have been used for their well known antimicrobial properties since ancient times (Chernousova & Eppele, 2013). In recent years, the use of silver has regained interest due to the emergence of multidrug-resistant organisms (MDROs) (Kresse *et al.*, 2007; Liu *et al.*, 2010; Thornton *et al.*, 2016). Silver is primarily used topically to treat chronic infections in burn wounds (deBoer *et al.*, 2015). The metal exerts its microbial toxicity by slowly releasing Ag^{I} ions that inflict damage on cell walls, produce reactive oxygen species and bind to DNA base pairs as well as proteins, impeding normal cellular functions (Liu *et al.*, 2010; Thornton *et al.*, 2016). As silver ions tend to precipitate as AgCl in the presence of blood plasma chloride (Chernousova & Eppele, 2013), there is a need for stable silver complexes that can slowly and sustainably release silver ions into biological matrices. Herein we report the synthesis and characterization of a novel silver complex, $[\text{Ag}(\text{qPyr})_2]\text{CF}_3\text{SO}_3$ [where $\text{qPyr} = 1\text{-}(\text{quinoline-2-ylmethylene})\text{aminopyrene}$] which could serve as a stable complex for the delivery of silver. In the design of this compound, qPyr was included due to its characteristic absorption and emission profile, which could allow tracking of the ligand and silver within the cell membrane of the bacteria (Ray *et al.*, 2006).

2. Structural commentary

The molecular structure of the cation in the title complex is shown in Fig. 1. The coordination environment of the Ag^{I} atom in the cationic complex is distorted tetrahedral (Table 1). The qPyr ligand binds to the metal in a bidentate fashion. In this complex, the chelate rings composed of atoms Ag1 , N2 , C8 , C9 , N1 and Ag1 , N4 , C34 , C35 , N3 are reasonably planar,

Table 1

Selected geometric parameters (Å, °).

Ag1–N3	2.249 (4)	Ag1–N4	2.411 (4)
Ag1–N1	2.228 (4)	Ag1–N2	2.399 (4)
N3–Ag1–N4	72.24 (15)	N1–Ag1–N4	119.33 (15)
N3–Ag1–N2	120.45 (15)	N1–Ag1–N2	73.09 (15)
N1–Ag1–N3	151.52 (16)	N2–Ag1–N4	131.88 (14)

with mean deviations of 0.054 (3) and 0.059 (3) Å, respectively. The dihedral angle between these two chelate planes is 69.0 (4)°. The two quinoline fragments within the qPyr ligand in the title complex are satisfactorily planar, with mean deviations of 0.031 (4) and 0.035 (4) Å. The dihedral angles between the quinoline moieties and the pyrene rings are quite similar [73.5 (4) and 73.8 (3)°].

3. Supramolecular features

The packing pattern exhibits the presence of both intra- and intermolecular offset π – π stacking interactions (Figs. 2 and 3). The extent of the intermolecular π – π interaction is found to be relatively stronger [3.543 (5) Å] compared to the intramolecular π – π stacking interactions [3.642 (5) and 3.617 (5) Å]. In both cases, the angle between the ring normal and the vector between the ring centroids is close to 20° and centroid-to-centroid distances are within the upper limit of 3.8 Å (Janiak, 2000). The crystal packing of the complex reveals also a non-classical hydrogen-bonding interaction (Steiner, 1996) of the type C–H...O between the cation and

the triflate anion (Table 2, Fig. 4). The arrangement of the two types of molecules along the *c* axis is shown in Fig. 5.

4. Database survey

A search of Cambridge Structural Database (Groom *et al.*, 2016) revealed that molecular systems where Ag¹ resides in a distorted tetrahedral coordination environment are primarily of a supramolecular nature. In a relatively recent report, two discrete Ag complexes, namely [Ag(HL¹)₂](PF₆) and [Ag(HL¹)₂](NO₃)(H₂O) (where HL¹ = (*n*-Py)–CH=N–

Table 2

Symmetry code: (i) $x - 1, -y + \frac{3}{2}, z - \frac{1}{2}$.

C₁₀H₆–COOH) are reported (Lee & Lee, 2013) which are structurally similar to the title complex. Both these molecules adopt triclinic symmetry in space group $P\bar{1}$. The average Ag–N distances for these complexes are slightly longer (2.349 and 2.346 Å) than that of the title complex (2.322 Å). Unlike the present complex, these two Ag complexes are characterized by significant intramolecular O–H···F and O–H···O hydrogen-bonding interactions with the PF₆[−] and NO₃[−] counter-ions. In another report, three Ag complexes, namely [Ag(**1**)₂](NO₃), [Ag(**1**)₂](PF₆) and [Ag(**1**)₂](OTf) [where **1** = (*R*)-2-(pyridin-2-ylmethylimino)-2′-(dimethylamino)-1,1′-binaphthyl] are described with similar structural features (Zhang *et al.*, 2011). In this study, [Ag(**1**)₂](NO₃) and [Ag(**1**)₂](PF₆) crystallize in space group $P2_12_12_1$ while [Ag(**1**)₂](OTf) crystallizes in $P2_1$. Here the Ag–N distances span the range 2.354–2.376 Å, noticeably longer than that of the title complex.

5. Synthesis and crystallization

Synthesis of the qPyr ligand

A solution of 1-pyrenecarboxaldehyde (115 mg, 0.50 mmol) in 10 ml of dichloromethane was added drop wise to a solution of 8-aminoquinoline (72 mg, 0.50 mmol) in 10 ml of methanol. The mixture was heated to reflux for 16 h and then concentrated under reduced pressure. The precipitate thus formed was collected by vacuum filtration affording 162 mg (91% yield) of *N*-(1-pyrene)-1-quinolin-2-ylmethanimine (qPyr) as a light-brown powder.

Synthesis of the title complex

Two equivalents of qPyr (100 mg, 0.28 mmol) were dissolved in 20 ml of 1:1 methanol:dichloromethane along with one equivalent of silver trifluoromethanesulfonate (36 mg, 0.14 mmol). The reaction mixture was then stirred for 12 h. After this time, the solution was concentrated under reduced

pressure. The resulting precipitate was collected through vacuum filtration affording a light-yellow powder. This powder was recrystallized from methanol to obtain [Ag(qPyr)₂]CF₃SO₃ as a light yellow–brown powder (124 mg, 91%). Single crystals were obtained by vapor diffusion of ethyl ether into a solution of [Ag(qPyr)₂]CF₃SO₃ in methanol.

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 3. Hydrogen atoms were included in calculated positions on the C atoms to which they are bonded, with C–H = 0.93 Å and *U*_{iso}(H) = 1.2*U*_{eq}(C).

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
