The title compounds, C₉H₁₂O₆ and C₁₀H₁₄O₆, were formed by careful hydrolysis of the corresponding diethyl esters. Their single crystals were grown from an ethyl acetate/hexane mixture. Crystals of both compounds have monoclinic (*P*2₁) symmetry with a single molecule in the asymmetric unit. Both crystal structures are very similar and display four –CO–OH · · · O=C(OH)– hydrogen bonds, forming a two-dimensional double-layered framework.

1. Chemical context

Transition-metal catalysis has developed as a powerful tool to create a variety of carbon–carbon and carbon–heteroatom bonds. Enantioselective versions of these reactions are especially interesting in the light of the possible pharmaceutical applications. The general route to such processes supposes the use of transition metal complexes with chiral ligands (Yang *et al.*, 2017). Therefore, easily accessible ligands of this type are of great importance for homogenous catalysis. Chiral phosphine ligands and amino acids are the most popular in this respect (Crassous, 2009). Examples of chiral carboxylate ligands are also known (Saget *et al.*, 2012), which can be useful in the synthesis of chiral coordination compounds and materials derived from them (Lam *et al.*, 2011). Various tartaric acid derivatives, which are also used in organic synthesis as chiral auxiliary agents to create chiral building blocks (Kassai *et al.*, 2000; Seebach *et al.*, 2001), might be particularly useful in solving the stated problem. Herein we report the synthesis and structures of two tartaric acid derivatives that may potentially be used as synthetic precursors of chiral transition-metal catalysts.

OPEN ACCESS

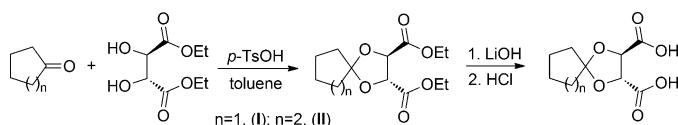

Figure 1
The synthesis of the title compounds (I) and (II).

Condensation of cyclopentanone or cyclohexanone with (2*R*,3*R*)-diethyl tartrate led to the formation of the corresponding ketals, careful hydrolysis of which allowed us to prepare the title acids (Fig. 1).

2. Structural commentary

The structures of tartaric acid derivatives (I) and (II) were found as anticipated (Figs. 2 and 3, respectively), having a single molecule in the asymmetric unit. The 1,3-dioxolane, cyclopentane [in (I)] and cyclohexane [in (II)] fragments have the usual conformations. The C—C, C—O and C=O bond lengths are within regular distances (Tables 1 and 2). A detailed structural and conformational analysis for the crystal structures of some related acetals $R'C_3H_3O_2(COR)_2$ ($R = \text{NH}_2, \text{OAlkyl}, \text{OH}$; substituent R' is at the 2-position of the 1,3-dioxolane ring) was given by Eissmann *et al.* (2012). Although the absolute structures of (I) and (II) cannot be unambiguously determined using the Flack parameter (Flack, 1983; Parsons, *et al.*, 2013) with the *SHELXL* program (Sheldrick, 2015), the chirality at carbon atoms C2, C3 (2*R*,3*R*) is initially known from their synthetic precursor (diethyl L-tartrate), and has been also confirmed for (2*R*,3*R*)-diethyl 1,4-dioxaspiro[4.5]decane-2,3-dicarboxylate, and for (II) by optical rotation measurements (see the experimental section). The molecules of (I) and (II) have very similar positions in the unit cells, making the structures nearly isomorphous, but the *c* axis in (II) is elongated by almost 1.5 Å compared with that in (I)

Table 1

O6—C5	1.441 (2)	C9—C10	1.538 (2)
C1—C2	1.529 (2)		

(see Table 5 below) because of the presence of an additional $-\text{CH}_2-$ unit in the cycloalkane fragment in (II) (see Fig. 4 for the alignment of the cycloalkane fragments in the unit cell).

3. Supramolecular features

The molecules of both structures are packed in two-dimensional frameworks by four $-\text{CO}-\text{OH} \cdots \text{O}=\text{C}(\text{OH})-$ hydrogen bonds between neighboring carboxyl groups (Tables 3 and 4). The packing diagrams for (I) (Figs. 4, 5a) are nearly identical to those of (II) (not shown). The molecules form double layers parallel to the *ab* plane and sterically shielded from other layers by the cycloalkane fragments (Fig. 4). Hydrogen-bonded chains within the same layer are formed via

two interactions involving the O1–H1 and O3 atoms of each molecule. These chains are interconnected into a two-dimensional hydrogen-bonded double-layered framework parallel to (001) by the O4–H4 and O2 atoms. The complicated structure of the two-dimensional double-layered framework is shown in Fig. 5a, but it can best be visualized in the simplified scheme in Fig. 5b. It might be noted that some weak C–H···O intermolecular interactions are also present (see the supporting information).

4. Database survey

Twenty crystal structures of tartaric acid ester derivatives possessing the 1,3-dioxolane cycle, $R'R''C_3H_2O_2(COOR)_2$, are

known to date [Cambridge Structural Database (CSD) Version 5.39, latest update Feb 2018; Groom *et al.*, 2016]. There are 10 crystal structures of esters bearing one substituent R' ($R'' = \text{H}$) at the 2-position of the 1,3-dioxolane fragment (acetals): CSD refcodes DAZJET (Lee *et al.*, 1999), LACREM, LACRUC (Roush *et al.*, 1992), LEPHAR, LEPHEV (Eissmann *et al.*, 2012), OLEGAN (Karisalmi *et al.*, 2003), WEGXOW (Belokon' *et al.*, 2005), XEYSEA (Jiang *et al.*, 2007), YAXHIQ (Lv *et al.*, 2012) and YIVGUF (Barrett *et al.*, 1995). The crystal structures of esters with two substituents R' and R'' (ketals) are represented by GAGHAY, GUHGUL (Pelphrey *et al.*, 2004), KEMRID (Wink & Dewan, 1990), MIWDIF (Ates & Curran, 2001), NAFWEW (Mikołajczyk *et al.*, 1996), QOTVUQ (Maezaki *et al.*, 2000), VICXOU/VICXOU10 (Giordano *et al.*, 1990; Ianelli *et al.*, 1992), VIHAL (Linker *et al.*, 2013) and VUCHAC, VUCHEG

**Figure 5**

(Ianelli *et al.*, 1992). The crystal structures of 14 related amide derivatives $R'R''C_3H_2O_2(\text{CONR}_2)_2$ are also known (see the CSD and also Eissmann *et al.*, 2012 and references therein). However, established crystal structures of related acids, $R'R''C_3H_2O_2(\text{COOH})_2$, are limited to only one structure with $R' = -\text{C}_6\text{H}_4\text{-COOH}$ and $R'' = \text{H}$ (LEPHIZ; Eissmann *et al.*, 2012). This fact can be explained by some subtle problems with the individual isolation of pure acid samples because of the facile hydrolysis of the 1,3-dioxolane fragment during their preparation. Therefore, the synthesis and especially the crystallization of $R'R''C_3H_2O_2(\text{COOH})_2$ acids is a challenging task.

5. Synthesis and crystallization

5.1. General experimental remarks

(+)-Diethyl L-tartrate [Sigma-Aldrich, >99%, found $[\alpha]_D^{297\text{K}} = +12^\circ$ (acetone, 20.5 mg ml $^{-1}$); lit. data $[\alpha]_D^{293\text{K}} = +10^\circ$ (ethanol, 53 mg ml $^{-1}$, see Černý, 1977] was used as purchased. ^1H and $^{13}\text{C}\{^1\text{H}\}$ NMR spectra were recorded with Bruker AM-300 and Bruker DRX-500 spectrometers in CDCl_3 (Cambridge Isotope Laboratories, Inc., 99.8% ^2H) and in acetone- d_6 (Sigma-Aldrich, 99.9 atom % ^2H).

5.2. Synthesis of ($2R,3R$)-diethyl 1,4-dioxaspiro[4.5]decane-2,3-dicarboxylate

A 1000 ml round-bottomed flask equipped with a reflux condenser and a Dean-Stark trap was charged with diethyl L-tartrate (85.56 ml, 500 mmol), cyclohexanone (51.82 ml, 500 mmol), toluene (600 ml) and *p*-toluenesulfonic acid monohydrate (2.80 g, 147 mmol). The mixture was refluxed for 62 h. The resulting dark-brown mixture was washed with a saturated aqueous solution of NaHCO_3 ($2 \times 100\text{ml}$) and with water ($2 \times 100\text{ml}$). The organic layer was dried over anhydrous Na_2SO_4 . The solvent was removed on a rotary evaporator. The obtained dark-brown oil was distilled under reduced pressure (388–391 K, 250 Pa). The yield of the colourless liquid was 84% (120.25 g, 420 mmol). $\eta_D^{293\text{K}} = 1.4625$, $[\alpha]_D^{297\text{K}} = -28.7$ (acetone, 20.5 mg ml $^{-1}$) [Lit. data $\eta_D^{293\text{K}} = 1.4605$, $[\alpha]_D^{293\text{K}} = -35.57$ (Tsuzuki, 1937)]. ^1H NMR (CDCl_3) δ : 1.12 (*t*, 6H, $\text{CH}_3\text{-CH}_2\text{-O}$), 1.30–1.45 (*m*, 10H, $-\text{C}_5\text{H}_{10}-$), 4.10 (*quartet*, 4H, $\text{CH}_3\text{-CH}_2\text{-O}$), 4.55 (*s*, 2H, CH).

5.3. Synthesis of ($2R,3R$)-diethyl 1,4-dioxaspiro[4.4]nonane-2,3-dicarboxylate

The synthesis of ($2R,3R$)-diethyl 1,4-dioxaspiro[4.4]nonane-2,3-dicarboxylate was carried out analogously to that of ($2R,3R$)-diethyl 1,4-dioxaspiro[4.5]decane-2,3-dicarboxylate, starting from 85.47 ml (500 mmol) of diethyl L-tartrate, 44.23 ml (500 mmol) of cyclopentanone, 600 ml of toluene and 2.80 g (14.7 mmol) of *p*-toluenesulfonic acid monohydrate. The yield of the colourless liquid after vacuum distillation (383–385 K, 265 Pa) was 78% (106.08 g, 390 mmol). ^1H NMR (CDCl_3) δ : 1.17 (*t*, 6H, $\text{CH}_3\text{-CH}_2\text{-O}$), 1.51–1.63 (*m*, 4H, $-\text{C}_4\text{H}_8-$), 1.64–1.77 (*m*, 2H, $-\text{C}_4\text{H}_8-$), 1.77–1.91 (*m*, 2H, $-\text{C}_4\text{H}_8-$), 4.12 (*quartet*, 4H, $\text{CH}_3\text{-CH}_2\text{-O}$), 4.57 (*s*, 2H, CH).

5.4. Synthesis and crystallization of ($2R,3R$)-1,4-dioxaspiro[4.5]decane-2,3-dicarboxylic acid, (II)

A 100 ml round-bottomed flask was charged with 2.130 g (7.52 mmol) of ($2R,3R$)-diethyl 1,4-dioxaspiro[4.5]decane-2,3-dicarboxylate, 22.5 ml of THF, 22.5 ml of methanol and 22.5 ml of 2 M aqueous solution of LiOH. The reaction mixture was stirred for 6 h. It was then washed with diethyl ether ($3 \times 20\text{ ml}$). The aqueous solution was acidified with a 2 M solution of HCl to pH ≈ 1 at 273 K. The formed acid was extracted with ethyl acetate ($3 \times 20\text{ ml}$). The organic layer was dried over Na_2SO_4 . The solution was removed on a rotary evaporator. The yield of the resulting white powder was 72% (1.250 g, 5.43 mmol). M.p. = 413 K, $[\alpha]_D^{297\text{K}} = -27.3$ (acetone, 20.5 mg ml $^{-1}$) [Lit. data $[\alpha]_D^{20} = -24.0$, ethanol, 304 mg ml $^{-1}$ (Innis & Lamaty, 1977)]. ^1H NMR (acetone- d_6) δ : 1.36–1.44 (*m*, 2H, $-\text{C}_5\text{H}_{10}-$), 1.53–1.74 (*m*, 8H, $-\text{C}_5\text{H}_{10}-$), 4.82 (*s*, 2H, CH), 7.0 (*br.s*, 2H, $-\text{COOH}$). $^{13}\text{C}\{^1\text{H}\}$ NMR (acetone- d_6) δ : 24.6, 25.6, 36.8, 77.7, 114.7, 171.7. Crystals of (II) were grown from an ethyl acetate/hexane (1:1 *v/v*) mixture.

5.5. Synthesis and crystallization of ($2R,3R$)-1,4-dioxaspiro[4.4]nonane-2,3-dicarboxylic acid, (I)

The synthesis of (I) was carried out analogously to that of (II), starting from 2.723 g (10 mmol) of ($2R,3R$)-diethyl 1,4-dioxaspiro[4.4]nonane-2,3-dicarboxylate, 22.5 ml of THF, 22.5 ml of methanol and 22.5 ml of 2 M aqueous solution of LiOH. The yield of the resulting white powder was 50% (1.081 g, 5 mmol). ^1H NMR (acetone- d_6) δ : 1.59–1.72 (*m*, 4H, $-\text{C}_4\text{H}_8-$), 1.74–1.87 (*m*, 2H, $-\text{C}_4\text{H}_8-$), 1.90–2.02 (*m*, 2H, $-\text{C}_4\text{H}_8-$), 4.78 (*s*, 2H, CH), 7.5 (*br.s*, 2H, $-\text{COOH}$). $^{13}\text{C}\{^1\text{H}\}$ NMR (acetone- d_6) δ : 24.0, 37.4, 77.9, 123.6, 171.4. Crystals of (I) were grown from an ethyl acetate/hexane (1:1 *v/v*) mixture.

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 5. The positions of all non-H and the hydroxy H atoms were found from the electron difference density maps. These atoms were refined with individual anisotropic (non-H) or isotropic (hydroxy H) displacement parameters. The positions of the other H atoms were also found from the difference map but they were positioned geometrically (C–H distance = 0.99 Å for methylene, 1.00 Å for tertiary hydrogen atoms) and refined as riding atoms with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$. Reflection (001) in (II) was affected by the beam stop, and was therefore omitted from the refinement.

Acknowledgements

Data collection

Bruker SMART APEXII
 diffractometer
 Radiation source: fine-focus sealed tube
 Graphite monochromator
 ω scans
 Absorption correction: multi-scan
 (SADABS; Bruker, 2008)
 T_{\min} = 0.827, T_{\max} = 0.996

4142 measured reflections
 2455 independent reflections
 1914 reflections with $I > 2\sigma(I)$
 R_{int} = 0.030
 θ_{\max} = 29.0 $^\circ$, θ_{\min} = 2.9 $^\circ$
 h = -8→8
 k = -7→7
 l = -14→19

Refinement

Refinement on F^2
 Least-squares matrix: full
 $R[F^2 > 2\sigma(F^2)]$ = 0.043
 $wR(F^2)$ = 0.083
 S = 1.06
 2455 reflections
 144 parameters
 1 restraint

Primary atom site location: structure-invariant
 direct methods
 Secondary atom site location: difference Fourier
 map
 Hydrogen site location: mixed
 H atoms treated by a mixture of independent
 and constrained refinement

$$w = 1/[\sigma^2(F_o^2) + (0.031P)^2]$$

where $P = (F_o^2 + 2F_c^2)/3$

$(\Delta/\sigma)_{\max} < 0.001$

$$\Delta\rho_{\max} = 0.29 \text{ e } \text{\AA}^{-3}$$

$$\Delta\rho_{\min} = -0.24 \text{ e } \text{\AA}^{-3}$$

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R-factor wR and goodness of fit S are based on F^2 , conventional R-factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\text{sigma}(F^2)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on F^2 are statistically about twice as large as those based on F , and R-factors based on ALL data will be even larger.
