**Keywords:** crystal structure; Hofmann clathrate; iron(II).**Supporting information:** this article has supporting information at journals.iucr.org/e

In the title polymeric complex,  $\{[\text{FePt}(\text{CN})_4(\text{H}_2\text{O})_2] \cdot 2\text{C}_3\text{H}_6\text{O}\}_n$ , the  $\text{Fe}^{\text{II}}$  cation has an octahedral  $[\text{FeN}_4\text{O}_2]$  geometry being coordinated by two water molecules and four cyanide anions. The Pt cation is located on an inversion centre and has a square-planar coordination environment formed by four cyanide groups. The tetracyanoplatinate anions bridge the  $\text{Fe}^{\text{II}}$  cations to form infinite two-dimensional layers that propagate in the  $bc$  plane. Two guest molecules of acetone per  $\text{Fe}^{\text{II}}$  are located between the layers. These guest acetone molecules interact with the coordinated water molecules by  $\text{O}-\text{H} \cdots \text{O}$  hydrogen bonds.

## 1. Chemical context

Hofmann clathrates and their analogues form one of the most famous families of compounds that are able to incorporate guest molecules. The first clathrate was obtained by Hofmann and Küspert in 1897 (Hofmann & Küspert, 1897) and was of composition  $[\text{Ni}(\text{NH}_3)_2\text{Ni}(\text{CN})_4] \cdot 2\text{C}_6\text{H}_6$ . It was a 2D coordination compound formed by infinite cyanometallic layers that propagate along the  $ab$  plane. The 2D system was supported by ammine axial ligands, and guest molecules of benzene were trapped between the layers.

Later, by slight modifications of the chemical composition, several analogous compounds were obtained, leading to the creation of a new class of coordination materials. The first modification was the substitution of nickel with other transition metals, as well as the introduction of other small aromatic guest molecules that resulted in the creation of compounds with the general formula  $[M(\text{NH}_3)_2M'(\text{CN})_4] \cdot 2G$  (where  $M = \text{Mn, Fe, Co, Ni, Cu, Zn, Cd}$ ,  $M' = \text{Ni, Pd, Pt}$  and  $G = \text{benzene, pyrrole, thiophene, aniline, biphenyl, etc.}$ ; Iwamoto, 1996). The second modification of the Hofmann clathrate was the substitution of square-planar  $\{M'(\text{CN})_4\}^{2-}$  anions with tetrahedral ( $\{M'(\text{CN})_4\}^{2-}$ ,  $M' = \text{Cd, Hg}$ ; Arcís-Castillo *et al.*, 2013), linear ( $\{M'(\text{CN})_2\}^-$ ,  $M' = \text{Cu, Ag, Au}$ ; Gural'skiy, Golub *et al.*, 2016; Gural'skiy, Shylin *et al.*, 2016), octahedral ( $\{M'(\text{CN})_6\}^{3-}$ ,  $M' = \text{Co, Cr}$ ; Dommann *et al.*, 1990) and even dodecahedral ( $\{M'(\text{CN})_8\}^{4-}$ ,  $M' = \text{W, Nb}$ ; Ohkoshi *et al.*, 2013) fragments. Additionally, a very important modification was made by the introduction of other organic ligands instead of ammonia. For example, by the introduction of pyridine, the first  $\text{Fe}^{\text{II}}$ -based clathrate  $[\text{Fe}(\text{py})_2\{\text{Pt}(\text{CN})_4\}]$  exhibiting spin-crossover (SCO) behaviour was obtained by Kitazawa *et al.* (1996). At the same

time, the introduction of various bidentate ligands such as pyrazine (Niel *et al.*, 2001; Gural'skiy, Shylin *et al.*, 2016), pyrimidine (Agustí *et al.*, 2008), bis(4-pyridyl)acetylene (Agustí *et al.*, 2008) and others allowed the formation of 3D SCO networks.

Additionally, the characteristics of spin transition in coordination compounds are known to be extremely sensitive to any changes in the chemical environment. As Hofmann clathrate analogues are very easy to modulate, numerous SCO complexes with very different temperatures, abruptnesses and hystereses of SCO were obtained. Moreover, the ability of Hofmann clathrate analogues to incorporate guest molecules provided SCO-based chemical sensors (Ohba *et al.*, 2009).

Herein we present a new Fe–Pt Hofmann clathrate analogue  $[\text{Fe}(\text{H}_2\text{O})_2\{\text{Pt}(\text{CN})_4\}] \cdot 2(\text{CH}_3)_2\text{CO}$ .

**Figure 1**  
A fragment of the molecular structure of the title compound showing the atom-labelling scheme. Displacement ellipsoids are drawn at the 50% probability level [symmetry codes: (i)  $x, -y, 1 - z$ ; (ii)  $-x, -y, z$ ; (iii)  $x, -y, z$ ; (iv)  $-x, y, z$ ; (v)  $-1 + x, -y, z$ ; (vi)  $-1 + x, -y, -z$ ; (vii)  $1 - x, y, 1 + z$ ; (viii)  $1 - x, y, 1 - z$ ].

## 2. Structural commentary

The title compound crystallizes in the  $P4/mmm$  space group. The  $\text{Fe}^{\text{II}}$  cation has a  $[\text{FeN}_4\text{O}_2]$  coordination environment (Fig. 1) comprising four  $\text{CN}^-$  anions in the equatorial positions [ $\text{Fe1} - \text{N1} = 2.158(5) \text{ \AA}$ ] and two water molecules in the axial positions [ $\text{Fe1} - \text{O1} = 2.130(6) \text{ \AA}$ ]. The  $\text{Fe} - \text{O}$  bonds are slightly shorter than the  $\text{Fe} - \text{N}$  bonds, thus leading to a compressed octahedral geometry. Judging by the bond length, the  $\text{Fe}^{\text{II}}$  cation is in a high-spin state at the experimental temperature (180 K). This is corroborated by the presence of  $\text{H}_2\text{O}$  molecules in the coordination sphere of  $\text{Fe}^{\text{II}}$ . The cyanide anions connect the  $\text{Fe}^{\text{II}}$  and  $\text{Pt}^{\text{II}}$  cations into infinite two-dimensional layers. The  $\text{Pt}^{\text{II}}$  cation is located at a fourfold rotation axis and possesses a square-planar geometry [ $\text{Pt1} - \text{C1} = 1.993(6) \text{ \AA}$ ,  $\text{C1} - \text{Pt} - \text{C1} = 90^\circ$ ]. Thanks to the tetragonal symmetry of the crystalline compound, no deviation from an ideal octahedron is observed for  $\text{Fe}^{\text{II}}$ ,  $\Sigma|90 - \theta| = 0^\circ$ , where  $\theta$  is the  $\text{N} - \text{Fe} - \text{N}$  or  $\text{O} - \text{Fe} - \text{N}$  angles. Additionally, the compound incorporates two guest molecules of acetone per  $\text{Fe}^{\text{II}}$  centers.

## 3. Supramolecular features

The crystalline structure is connected by bridging tetracyanoplatinate moieties, which form a two-dimensional grid that propagates along the  $ab$  plane (Fig. 2). As imposed by

**Figure 2**  
View of the crystal structure of the title compound in the  $bc$  plane showing the two-dimensional cyanometallic layers. Hydrogen bonds are shown as dashed lines. Acetone H atoms are omitted for clarity.

**Table 1**  
Hydrogen-bond geometry (Å, °).

$D-H\cdots A$	$D-H$	$H\cdots A$	$D\cdots A$	$D-H\cdots A$
$O1-H1A\cdots O2^i$	0.84	2.03	2.775 (11)	147
$O1-H1A\cdots O2^{ii}$	0.84	2.03	2.775 (11)	148
$O1-H1B\cdots O2^{iii}$	0.85	2.04	2.775 (11)	144

Symmetry codes: (i)  $-x+1, -y, z$ ; (ii)  $-x+1, y, -z$ ; (iii)  $-y, -x+1, -z$ ; (iv)  $y, -x+1, z$ .

symmetry, no deviation from linearity for the Fe–N–C–Pt linkages is observed [ $Fe-N-C = 180^\circ$ ,  $N-C-Pt = 180^\circ$ ,  $C-Pt-C = 180^\circ$ ]. The distance between parallel cyanometallic layers is 7.973 (6) Å. The guest acetone molecules are located between the cyanometallic layers. Each oxygen atom of the coordinated water molecules interacts with acetone by O–H···O hydrogen bonds (Fig. 3, Table 1), creating a three-dimensional supramolecular framework. The size of the available voids between the cyanometallic layers allows the acetone molecules to rotate freely, thus leading to disorder of the acetone molecules over four positions.

#### 4. Database survey

A survey of the Cambridge Structural Database (Version 5.38; Groom *et al.*, 2016) confirmed that the title compound has never been published before. It revealed 51 cyanometallic structures of the general formula  $[TM(H_2O)_2\{TM(CN)_4\}]$ , where  $TM$  = any transition metal. There were also 19 hits for structures containing  $[Fe\{Pt(CN)_4\}]$  fragments: refcodes: OVILEM, OVIRUI, OVIRUI01, OVIRUI02 and OVIRUI03 (Sciortino *et al.*, 2017), AMIJOX (Kucheriv *et al.*, 2016), BEDWEO and BEDWIS (Sciortino *et al.*, 2012), CEMYUO

**Figure 3**

#### 5. Synthesis and crystallization

Crystals of the title compound were obtained by slow diffusion (three layers) in a 3 ml tube. The first layer contained 19 mg (0.05 mmol) of  $K_2[Pt(CN)_4]$  in 0.5 ml of water. The middle layer contained 1.5 ml of a water:acetone (1:1) solution. The third layer contained 25 mg (0.05 mmol) of  $Fe(OTs)_2\cdot 6H_2O$  in 0.4 ml of acetone and 0.1 ml of water. The colourless crystals grew in the middle layer within three weeks and were kept in the mother solution prior to measurements.

#### 6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. All hydrogen atoms were fixed at calculated positions and refined as riding with  $C-H = 0.96$  Å and  $O-H = 0.84$  Å,  $U_{iso}(H) = 1.5U_{iso}(C, O)$ . The OH group and the idealized methyl group were refined as rotating.

*Special details*

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
