## Crystal structure of bis(mesityl)(pyrrol-1-yl)borane

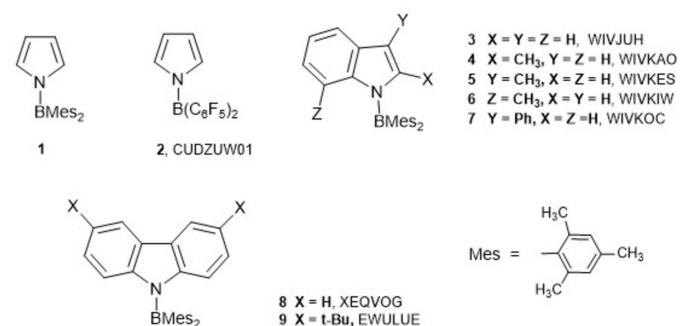

Onur Sahin<sup>‡</sup> and John D. Wallis\*

School of Science and Technology, Nottingham Trent University, Clifton Lane, Nottingham, NG1 8NS, United Kingdom.  
\*Correspondence e-mail: john.wallis@ntu.ac.uk

In the crystal structure of the title compound,  $C_{22}H_{26}BN$ , the B atom acts to reduce the delocalization of the nitrogen lone-pair electron density into the pyrrole ring, so that the two N–C bonds increase in length to 1.4005 (14) and 1.3981 (14) Å. The N–B bond length is 1.4425 (15) Å, which is longer than a typical N–B bond because the nitrogen lone pair is not fully available to participate in the bond.

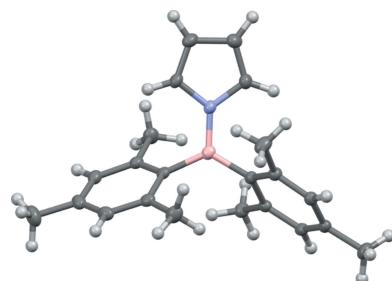

### 1. Chemical context

The structure of the title compound **1** is of interest because of the effect of the bis(mesityl)boron group on the electronic structure of the pyrrole, since the nitrogen lone pair, which is essential to the heterocycle's aromatic  $6\pi$  system, now has the possibility of being donated to the boron atom. This molecule has been investigated previously for its fluorescence, and shows a large Stokes shift, which involves twisted intramolecular charge transfer (TICT) of the excited state, by rotation about the N–B bond (Brittelli & Eaton, 1989; Cornelissen & Rettig, 1994; Cornelissen-Gude & Rettig, 1999). It has been used recently in the preparation of conductive polymers (Wildgoose *et al.* 2019).

### 2. Structural commentary

The crystal structure of bis(mesityl)(pyrrol-1-yl)borane **1** was determined at 120 K and the molecular structure is shown in Fig. 1. The bonding geometries at both the boron and nitrogen atoms are almost planar, with an angle of 16.13 (8)° between these two bonding planes. The N and B atoms lie 0.0351 (11) and 0.0285 (13) Å, respectively, out of the planes defined by their three attached atoms. The planes of the two mesityl groups lie at 58.53 (3) and 61.46 (4)° to the boron atom's bonding plane, and so there is limited donation of their  $\pi$ -electron densities to boron. These dispositions are controlled by the need to maintain separations between their two adj-

C $_{\beta}$ —C $_{\beta}$	1.4290 (17)	1.423 (3)	1.425	1.4418 (9)	1.430

Notes: (a) RUVQII (Goddard *et al.*, 1997); (b) Lee & Boo (1996); (c) CUDZUW01 (Flierler *et al.*, 2009); (d) Averaged data for structures containing C-unsubstituted-N-carbonyl pyrrole fragments measured at  $T < 150\text{ K}$  [BEFFUQ (Hatano *et al.*, 2016), BOKSUR (Ariyarathna & Tunge, 2014), CIFNIR (O'Brien *et al.*, 2018) and LAQFER (Uraguchi *et al.*, 2017).

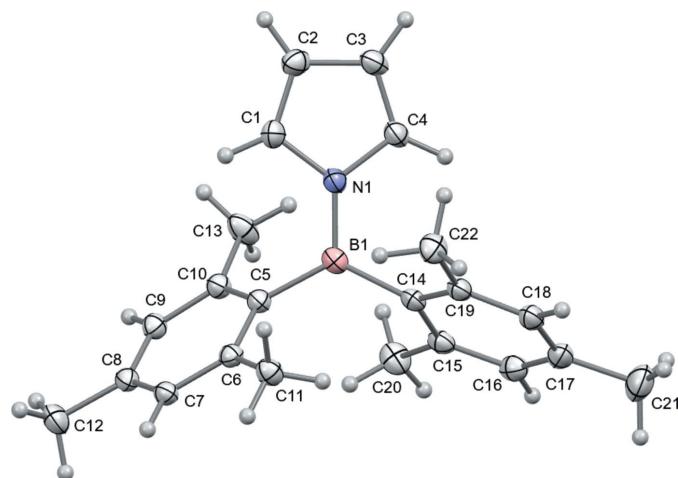

cent pairs of *ortho* methyl groups [ $\text{H}_3\text{C}\cdots\text{CH}_3 = 3.610 (3)$  and  $3.736 (3)\text{ \AA}$ ], and is supported by the widening of the C—B—C bond angle [ $125.18 (9)^\circ$ ], compared to the two N—B—C bond angles [ $118.30 (10)$  and  $116.42 (9)^\circ$ ]. The mesityl groups' planes lie at  $77.14 (4)^\circ$  to each other, and at  $69.18 (3)$  and  $67.06 (4)^\circ$  to the pyrrole ring's best plane. The hydrogen atoms of three methyl groups (C12, C13 and C21) were modelled in two orientations. The positions and displacement parameters of hydrogen atoms on the pyrrole ring were refined, and for those attached to the C $_{\alpha}$  atoms, the H—C $_{\alpha}$ —C $_{\beta}$  angle showed widening to  $131\text{--}132^\circ$ , similar to that in pyrrole (Goddard *et al.*, 1997; Lee & Boo, 1996).

The N—B bond is  $1.4425 (15)\text{ \AA}$  long. This is *ca*  $0.04\text{ \AA}$  longer than in similar compounds where the nitrogen atom is attached to two  $sp^3$  carbon atoms [ROCRAD (two molecules; Morawitz *et al.*, 2008), TAYYAV (Araki *et al.*, 2012), UWUFID (Smith *et al.*, 2016), YOMKAM (Khasnis *et al.*, 1995);  $T \leq 173\text{ K}$ , N—B range  $1.388 (2)\text{--}1.412 (3)\text{ \AA}$ , average  $1.40\text{ \AA}$ ] and where the nitrogen lone pair is fully available for donation to boron. Compared to the molecular geometry of pyrrole itself, as determined by X-ray crystallography at  $103\text{ K}$  (Goddard *et al.*, 1997) and by calculation at the B3LYP-631G\* level (Lee & Boo, 1996), the most notable difference is in the increase of the two N—C bond lengths to  $1.4005 (14)$  and  $1.3981 (14)\text{ \AA}$  from  $1.365 (2)\text{ \AA}$  (experimental) and  $1.376\text{ \AA}$  (calculated) (Table 1). The C $_{\alpha}$ —C $_{\beta}$  bond lengths are

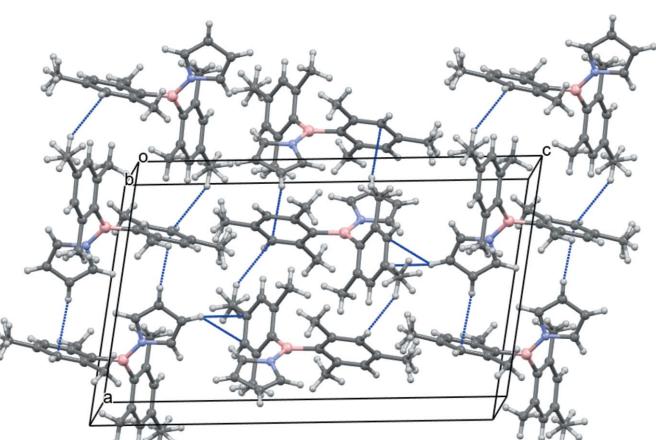

$1.3536 (16)$  and  $1.3514 (17)\text{ \AA}$  and the C $_{\beta}$ —C $_{\beta}$  bond length is  $1.4290 (17)\text{ \AA}$ . Thus, in contrast to pyrrole, the N—C $_{\alpha}$  and C $_{\alpha}$ —C $_{\beta}$  bonds are no longer similar in length, due to a reduction in the contribution of the nitrogen atom's lone pair to the electronic  $\pi$  system of the pyrrole ring. When the mesityl groups are replaced by pentafluorophenyl groups in derivative **2**, the N—B bond is considerably shorter than in **1** [ $1.4094 (9)$  cf.  $1.4425 (15)\text{ \AA}$ ] due to greater lone-pair donation from nitrogen towards the more electron-deficient boron. Consequently, compared to **1**, the pyrrole ring shows slightly longer N—C bonds [ $1.4033 (6)\text{ \AA}$ ] and a longer C $_{\beta}$ —C $_{\beta}$  bond [ $1.4418 (9)\text{ \AA}$ ], though similar lengths for the C $_{\alpha}$ —C $_{\beta}$  bonds [ $1.3553 (6)\text{ \AA}$ ] (Table 1). For comparison, the effect of boron on the pyrrole ring in **1** is similar to that when the pyrrole nitrogen atom is substituted with a carbonyl group to form an amide (Table 1).

### 3. Supramolecular features

The molecules are packed in layers in the *ab* plane (Fig. 2). There are no particularly short intermolecular contacts, consistent with the low density of the crystal ( $1.132\text{ g cm}^{-3}$ ). Within a layer, the molecules are related by centres of symmetry and translations along *a* and *b*. Adjacent layers are related by the twofold screw and *n*-glide planes. The four shortest intermolecular C···H distances are in the range  $2.81\text{--}2.83\text{ \AA}$ . Two of these involve the *meta*-C atom, C18, with a

**Figure 1**

The molecular structure of **1**, with anisotropic displacement parameters drawn at the 50% probability level. Only the more populated orientations for methyl groups C12, C13 and C21 are shown.

**Figure 2**

The crystal-packing arrangement for **1**, viewed down the *b* axis, with the shortest C···H separations ( $2.81\text{--}2.83\text{ \AA}$ ) shown in blue. Both orientations of the H atoms on methyl groups C12, C13 and C21 are shown.

methyl hydrogen atom and a pyrrole ring's hydrogen atom, which are directed to opposite sides of the phenyl ring [C18 $\cdots$ H12A( $1 - x, 1 - y, 1 - z$ ) and C18 $\cdots$ H3( $-x, 2 - y, 1 - z$ )]. The two others involve both a *meta* and a *para*-C atom of the second phenyl ring and the pyrrole hydrogen atom H2 [C8 $\cdots$ H2( $\frac{1}{2} - x, y - \frac{1}{2}, \frac{3}{2} - z$ ) and C9 $\cdots$ H2( $\frac{1}{2} - x, y - \frac{1}{2}, \frac{3}{2} - z$ )].

#### 4. Database survey

The structure of the analogue of **1** bearing two 2'-thienyl groups in the pyrrole's 2- and 5-positions (XEQVUM; Taniguchi *et al.*, 2013) shows a larger angle ( $35.1^\circ$ ) between the bonding planes at nitrogen and boron due to avoidance of steric interactions between the thiophene and mesityl groups, and has a longer N–B bond [ $1.472$  (7) Å] though the structure has lower precision. Room-temperature measurements on a series of five indole analogues of bis(mesityl)pyrroloborane, **3–7**, show angles of  $22.4$ – $32.4^\circ$  between the two bonding planes and slightly longer N–B bonds [ $1.442$  (3)– $1.457$  (3) Å] with a correlation between the increasing angle between bonding planes and longer N–B bonds (Cui *et al.*, 2007). Two carbazole analogues, **8** and **9**, show interplanar angles between the two bonding planes of  $23.1$  and  $27.9^\circ$  and N–B bond lengths of  $1.442$  (3) and  $1.440$  (3) Å, similar to those in **1** (Taniguchi *et al.*, 2013; Weber *et al.*, 2011). All structures are reported in the Cambridge Structural Database, release 2021.3 (Groom *et al.*, 2016).

#### 5. Synthesis and crystallization

A solution of pyrrole (0.25 g, 3.7 mmol) in THF (10 mL) under nitrogen was treated with sodium hydride (60% dispersion in oil, 0.16 g, 4.0 mmol) and the mixture stirred at 293 K for 2 h. Dimesitylboron fluoride (CARE: gives HF with moisture) (1.09 g, 4.07 mmol) in dry THF (10 mL) was added at room temperature. The mixture was left to stir overnight. The bright orange–yellow mixture was quenched with water (20 mL), extracted with ether ( $2 \times 30$  mL) and the combined organic phase was dried over  $\text{MgSO}_4$ . The crude material was purified by column chromatography ( $\text{SiO}_2$ ) using hexane: dichloromethane (8:1) as eluent to give **1** (0.76 g, 65%) as a slightly oily white solid, from which crystals were grown using ethyl acetate, m.p. 411 K.  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ ) [ppm]:  $\delta = 6.84$  (4H, s,  $2 \times 3'$ – $5'$ -H),  $6.81$  (2H, t,  $J = 2.2$  Hz, 2-,5-H),  $6.37$  (2H, t,  $J = 2.2$  Hz, 3-,4-H),  $2.32$  (6H, s,  $2 \times 4'$ -CH<sub>3</sub>),  $2.11$  (12H, s,  $2 \times 2'$ –, 6'-CH<sub>3</sub>);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ ) [ppm]:  $\delta = 141.7$  ( $2 \times 2'$ –, 6'-C),  $139.0$  ( $2 \times 4'$ -C),  $136.5$  br ( $2 \times 1'$ -C),  $128.3$  ( $2 \times 3'$ –, 5'-C),  $126.5$  (2-, 5-C),  $114.6$  (3-, 4-C),  $22.8$  (2  $\times$  2'-, 6'-CH<sub>3</sub>),  $21.5$  ( $2 \times 4'$ -CH<sub>3</sub>); IR (ATR): 2920, 2853, 1606, 1472, 1451, 1421, 1399, 1378, 1329, 1310, 1287, 1252, 1156, 1122, 1080, 1074, 1043, 1030, 850, 817, 763, 733, 717, 677, 656, 619, 560, 516 cm<sup>-1</sup>.

#### 6. Refinement

Crystal data and details of data collection and structure refinement are summarized in Table 2. Pyrrole H-atom posi-

**Table 2**  
Experimental details.

Crystal data	
Chemical formula	$\text{C}_{22}\text{H}_{26}\text{BN}$

Computer programs: *CrysAlis PRO* (Rigaku OD, 2022), *SHELXT2018/2* (Sheldrick, 2015a), *SHELXL2018/3* (Sheldrick, 2015b), *Mercury* (Macrae *et al.*, 2020) and *OLEX2* (Dolomanov *et al.*, 2009).

tions and displacement parameters were refined. All other H atoms were refined using a riding model with C–H bonds fixed at 0.95 Å for hydrogens attached to phenyl carbon atoms and at 0.98 Å for methyl hydrogen atoms. Three methyl groups were refined in two orientations (C12, C13 and C21). The isotropic atomic displacement parameters of the H atoms were set at  $1.2U_{\text{eq}}$  of the parent atom for aromatic groups and at  $1.5U_{\text{eq}}$  for methyl groups.

 Extinction coefficient: 0.0035 (4)

*Special details*

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
